With all these precedents, it seems hardly surprising that the validity of a new species described in 1977 was either doubted or rejected by most authors who discussed it; this was the so-called Green-billed Curassow ("*Crax estudilloi*"), described from a single aviary bird obtained as a captive chick in La Paz Department, Bolivia. Its unique character, the pale green base of the bill, has tentatively been attributed to an inappropriate diet, to developmental abnormalities or often to hybridization between the Bare-faced Curassow (*Crax fasciolata*) and some other species of *Crax*. Another curassow with a pale green bill, described by Sclater in 1875 as "*Crax viridirostris*", and perfectly illustrated in one of his publications, was also based on a captive bird, found in Amsterdam Zoo, and so it could have been the result of the same causes. It is interesting to note that hybrids of the Blue-billed Curassow with both the Great and Bare-faced Curassows has a green cere, but it seems rather unlikely that individuals of this Colombian endemic could be found captive in Bolivia. Also, it seems that some features noted in the captive bird were quite distinctive, espe-

The Plain Chachalaca owes its common name to its colouring, not to the type of habitat it occupies! In fact, the genus *Ortalis*, to which all the chachalacas belong, is noteworthy for plain coloration and small size, as well as a lack of wattles, caruncles or any other type of embellishment on the head, although there is bare skin on the throat. These characteristics have led to the chachalacas' being considered the most primitive members of the family, for which reason they are placed at the beginning of the taxonomic sequence.

[*Ortalis vetula mcallii*,
Texas, USA.
Photo: J. Davies/Aquila]

The most typical guans are the fifteen species of *Penelope*, the most diversified genus in the whole family. They have more striking plumage than the chachalacas and are larger, although they share the same slender body. In addition, in all species both sexes have a prominent bright red dewlap formed by the bare skin of the throat, as can be seen in this Rusty-margined Guan. This bird also shows the trait to which the species owes its common name, and which differentiates it from all the other guans, namely the rusty buff to chestnut fringes on the inner secondaries, scapulars and upperwing-coverts.

[*Penelope supercilialis*, Brazil.

cially the voice. Ultimately, all this lengthy theorizing calls for a field expedition to investigate the validity of this hypothetical new species.

Morphological Aspects

Cracids range from medium-sized, in the case of the chachalacas, to large, in the case of the curassows and some guans, with most guans occupying an intermediate position. The smallest species, the Buff-browed Chachalaca, has a total length of about 42 cm, while some Great Curassows in the northern part of the species' range reach 92 cm.

The general appearance of cracids is similar to that of other gallinaceous birds, and varies relatively little over the family as a whole. The body is heavy in all species, especially the curassows, while the chachalacas and the guans have a more slender build, which enables them to move more freely about in thick vegetation, as these species are more arboreal than the curassows. For example, while a male of the Great Curassow could easily weigh more than 4 kg, the Crested Guan, the largest *Penelope*, does not usually reach 2.5 kg, although it is only a little smaller lengthwise. This difference in body structure is related to the different pelvic proportions of the two, one of the features on which the division into two subfamilies is based (see Systematics).

The neck is long and the head small, often with a crest, which can be longer and more curved depending on the species; this is raised conspicuously when the bird is excited, and is apparently important in displays. In general, the bill is similar to a domestic chicken's and is normally medium-sized, though somewhat heavier in the curassows. However, in the four species of the genus *Mitu*, it is considerably modified, not in relation to any specialized diet, but rather as an element in display. In this genus the massive bill carries out the same function as the dewlaps, wattles, helmets and other ornaments that many other species have.

The legs are long and strong, longest in the curassows, again as an adaptation to their more terrestrial habits, and shortest in the guans, the most arboreal members of the family.

Unlike all other Galliformes, except the megapodes, cracids have an elongated hind toe on the same level as the three front toes, which is a perfect adaptation for perching in trees, and even the most terrestrial species often do so. Consequently, they are capable of moving adeptly among the branches, hopping from limb to limb, and can grasp even very thin branches. The chachalacas are even able to move through thick vegetation at great speed and with remarkable agility, using their wings to help, in a movement that appears to be half way between running and flying.

The legs are equally good for walking, and even the most arboreal species sometimes descend to the ground, at least in order to feed on fallen fruits or to drink. They walk elegantly with long steps, and can trot gracefully and even run, although not as fast as the more terrestrial Galliformes.

All species have a long tail and strongly rounded, concave wings. Their pectoral musculature is well developed, but their capacity for flight is moderate, and sustained flights are rare, but after a flurry of wingbeats they make long glides in which the long tail provides extra support. When they move long distances they normally glide, especially the guans. A bird loses height gradually and when it comes to a halt at the base of a tree, it climbs up again through the branches until it reaches the canopy from where it will throw itself off into a new glide. When startled, unlike many pheasants which tend to hide on the ground, most cracids fly away, even the larger species, although the curassows sometimes run away. Their flying ability is more than sufficient for making a quick escape, although when flushed the speed of their wingbeats is notably less than that of partridges, pheasants and other terrestrial Galliformes. Logically, the curassows are the poorest fliers, while the guans, especially the piping-guans (*Pipile*), are the best.

The consistency of the plumage is variable. It is generally soft, particularly in the chachalacas that live in warmer, drier areas than the other species, but it can be much more dense and compact, repelling water readily, in the species that live in cold rainy areas, such as cloud forests.

Coloration, although often attractive, is usually discreet, and in this sense camouflage has greater influence than display. The Nocturnal Curassow is an extreme case, as both sexes have

The Blue-throated Piping-guan and its congeners are the best fliers amongst the Cracidae. Notwithstanding, their normal method for travelling fair distances, in common with the other guans, is by means of lengthy glides on their broad, concave wings, while the long tail serves to provide extra support in the air. Once a gliding bird has lost height, it lands low in a tree, climbs up into the canopy and then sets off on a new glide.

barred, mottled, very cryptic plumage. The chachalacas have the dullest plumage, which is related to their less thickly wooded habitats. But even in these rather plain species there are some parts of the plumage that serve to make them more conspicuous, for example to keep the groups within visual contact, or for use in breeding displays. This is the function of the white or chestnut tail tips and the rich rufous primaries or head found in many chachalacas, and also of the white patches on the shoulders of the piping-guans.

In this family there are also plumages that have a definite display function. In most cases they are black with a greenish or bluish sheen above, often contrasting conspicuously with snowy white underparts. Delacour and Amadon came to the conclusion that cryptic plumage is ancestral in this family, while black or black and white represent a more advanced type selected for display. This evolutionary tendency nor-

mally takes place first in the male, but later in the female too, which is hardly surprising, given that some sexual displays in cracids are probably mutual (see Breeding), as is often the case in monogamous birds. According to this theory, species like the Highland Guan and the Great and Bare-faced Curassows, with the females notably more cryptic than the males, would have reached the first stage. Other species, notably the Wattled Curassow (*Crax globulosa*), in which the female is almost like the male but with the belly rufous instead of the more conspicuous white, would be gradually reaching the second stage. The Black Curassow (*Crax leucitor*) and the Northern Helmeted Curassow, amongst others, would have arrived fully at this stage, with the females practically identical to the males. In addition, the occurrence in the latter species of a brown barred morph that turns up sporadically in a few females can be considered a possible throwback to the original plumage of the female, and perhaps that of the male too.

Even in the species that have developed their plumage for display, the protective function is not lost. Obviously, the pure white feathers on the abdomen of several curassows are conspicuous, but they are only exhibited openly during courtship. The plumage is never brilliantly coloured, as is often the case with the facial skin, dewlaps, wattles and other appendages. These doubtless play a more important role than the plumage in displays performed at close quarters, but from a distance they are less conspicuous amidst the incredible diversity of forms and colours, especially of leaves, that dominate the interior of tropical forests.

While there are varying degrees of sexual dimorphism in the plumage of some curassows, in all chachalacas and all guans sexes are alike, with the remarkable exception of the Highland Guan, which shows considerable differences in the plumage and the dewlap. It is also the only species in the family in which females are larger than males. In all other species males average 5% larger than females, or rarely up to 10% larger. In some species iris colour differs with sex, for instance in the Dusky-legged Guan the iris is red in males but pale brown in females, but in other species, like the Rusty-margined Guan, both sexes have a red iris. Finally, the dewlap of the guans and piping-guans is, at least in some species such as the

The rare barred brown morph of the female Northern Helmeted Curassow. Note that this species does not normally show sexual dimorphism, with both sexes predominantly glossy black. This morph, with its cryptic plumage, has been interpreted as a possible throwback to a more ancestral, less evolved, plumage of the female.

[*Pauxi pauxi pauxi*.

Lynx]

The curassows are generally larger than the guans, with a noticeably more robust body, in line with their much more terrestrial habits. The Great Curassow is the largest member of the genus *Crax* and has the most developed crest. It also shows the greatest sexual dimorphism in the curassows: the male is always glossy black, with a snowy white lower abdomen; the female, in contrast, is polymorphic, with a dark, a red, and a barred morph, all of which share, however, the characteristic black and white cross-barring on the head and neck, which distinguishes them from any other member of the family. Furthermore, females of the dark morph, the commonest in the northern part of the species' range, show a very wide range of individual variation, with scarcely two birds alike. The tail may be uniformly black or dark chestnut, or vermiculated with white, whilst the upperparts may be uniform or mottled with buffy white or blackish brown. In any form, they can be distinguished from red morph females by having the mantle, lower throat and upper breast blackish, and by the fact that the tail never has the boldly barred pattern which characterizes the red morph. Nevertheless, the different morphs appear to blend more or less into one another through a series of intermediate individuals.

Black-fronted Piping-guan, somewhat larger and more brightly coloured in males than in females.

Juvenile plumage is generally very similar to that of adults, if somewhat duller and a little softer; it is assumed at a very early age, even when the young bird is still noticeably smaller than the adults. Observations of very small birds in apparently adult plumage even caused some early workers to consider some juveniles as new species. Again, the exception to the norm is the Highland Guan, as the male does not acquire the black adult plumage until its second year, up to which time it is similar to the female.

Some published records of brown juvenile plumages in other cracid species are apparently erroneous, prompted by the occasional appearance, unrelated to age, of brown feathers in the black plumage of some curassows. There are many other plumage aberrations, like the occurrence of white tail tips, or their absence in species that normally have them without this being the result of abrasion, or a yellowish instead of white abdomen, or partial albinism. In fact, all of these are quite usual in the cracids, as recently shown by D. M. Teixeira and H. Sick, who suggest that in some cases, rather than aberrations, some might more appropriately be considered cases of polymorphism. Some morphs are already known amongst female curassows: for instance the aforementioned brown barred morph in the Northern Helmeted Curassow; a rare black and white barred morph in the Blue-billed Curassow; and the dark and red morphs, and also a rare barred morph, all in the Great Curassow, and varying regionally in their occurrence. Some females of the Wattled

Curassow also present a marbled pattern on the wings very similar to that which normally characterizes the female of the Red-billed Curassow.

Little is known about moult, but it is probably normally rather slow, affecting only one or two feathers at a time, in both the wings and the tail. Consequently, a curassow's wing can show feathers of three different moult cycles at the same time. This strategy may be possible because the birds live in tropical areas, where food is plentiful all year round.

An interesting adaptation in all guans, except the Horned Guan, is the modification of the distal 5-8 cm of the quills on the three or four outermost primaries, which permits the birds to produce a strange, very loud noise during their characteristic wing-drumming or wing-whirring displays (see Breeding). The modification can consist of: bowing, with the narrow tip of the outermost primary being strongly incurved, as in the Crested Guan, one of the species with a fairly subtle modification; stronger bowing and stiffening, as in other species of *Penelope*; or even, in addition to the strong curvature, an abrupt narrowing of the tips, as in the genera *Chamaepetes*, with the three outer primaries emarginated, and *Pipile* and *Aburria*, with the four outer primaries emarginated. It is worth noting that the degree of modification is not related to the frequency of these displays. For example, the slightly modified Crested Guan is a vigorous drummer, while the very specialized Wattled Guan is notably less so, but in the display of the latter the quality and pitch of the sound produced are much more striking.

Another characteristic morphological adaptation related to sound production is the modification of the trachea in many species. This is responsible for increasing the volume and lowering the pitch of calls. The modification consists of a variable lengthening of the trachea and the formation of a loop between the skin and the pectoral muscles, sometimes even extending to the belly before returning to the thoracic cavity. In some *Crax* curassows, the trachea is also flattened, so that it can be more than twice as wide one way as the other. All male chachalacas and curassows have modified tracheas, including the Wattled Curassow, which has a whistling as opposed to booming voice (see Voice), so this adaptation would not seem to make sense. In the guans this modification is found only in the genus *Penelope*, in which there is great variation: Spix's Guan has a very large loop; the Dusky-legged Guan a short one; and the Crested, Cauca, Andean and Baudo Guans do not have one at all. In *Penelope* the modification is present in both sexes, although the trachea is somewhat shorter in females. In other bird groups with similar modifications, such as the swans (*Cygnus*) and the cranes (*Grus*), the adaptation occurs only in the male.

Another distinctive feature of the cracids is the brightly coloured bare skin, in the cere, dewlaps and various kinds of appendage, such as wattles, knobs, horny helmets or integument-covered tubercles. In the *Mitu* curassows it is actually the bill that is modified for the same reason, and in some guans and curassows the legs too are bright red. The chachalacas generally lack such adornments, although the bare skin of the throat and sometimes the face, while not protruding, is also an eye-catching red or pink.

The function of these modifications is probably related to sexual recognition and the maintenance of the pair-bond, while they may also be used in courtship display. Their presence in both sexes in all chachalacas and guans, except the peculiar Highland Guan, and also in most curassows suggests that displays are mutual in these species, as is typical in other monogamous birds like grebes or cranes. Recent field research with several *Crax* curassows, in which the absence of any direct male to male combat has been proved, suggests that these adornments do not play a part in the expulsion of rivals of the same sex.

The variety of all these sexual characters in this family is remarkable, especially in the case of the curassows. Even within the same superspecies, in which the adornments start from the cere in all species, there are two with brightly coloured ceres but hardly any growth, one in which the growth on the upper mandible is enlarged but not that on the lower, one in which the

Birds of the red (above) and barred (below) morphs of the female Great Curassow. The relative abundance of each colour morph varies geographically, but this does not imply subspecific variation. The red morph is the only one known in the South American part of the species' range, but it is also found as far north, at least, as Honduras. The dark morph predominates in Mexico, but also occurs as far south as southern Costa Rica. The barred morph, the least common of the three, has only been recorded between the Isthmus of Tehuantepec and the Yucatán Peninsula, but always more sporadically than the dark morph.

[*Crax rubra rubra*.

Photos: Josep del Hoyo/Lynx]

opposite occurs, and three in which the knobs grow from both mandibles; all this varies through bright yellow and orange to red or blue. The enormous diversity of sexual adornments in this family is further proof that in the process of natural selection similar effects can be achieved by different paths.

But what are the evolutionary forces that influence the development of these extravagant adaptations? A recent study of the Yellow-knobbed Curassow by R. Buchholz shows a correlation between the age of males and the size of their knobs and wattles. It is supposed that in long-lived species like curassows, females prefer to mate with older males because these individuals have demonstrated their capacity for survival and they would transmit better genetic stock to their descendants. Thus, the size of these adornments might be used by females when choosing their mates, at least in some species, so they would be sexually selected.

Wattles, dewlaps and other areas of bare skin seem to be very small in some species of montane cloud forest, where night temperatures can be very low. Both the Andean and Bearded Guans have a partly feathered throat, and also the upper half of the tarsus. The Wattled and Horned Guans, also mountain species, likewise have much smaller areas of bare skin on the throat than do tropical guans. Once more, the Highland Guan is an exception, since the male has one of the largest dewlaps in the family, but the species inhabits mountains where night temperatures can be chilly.

Habitat

The cracids are essentially forest birds, which is hardly surprising as they are the only arboreal family in Galliformes. However, while the guans and curassows are found almost exclusively in forest, the chachalacas, although never present in arid areas or grasslands, are adapted for life in more open woodlands, and even in areas with few trees, as long as there is abundant bushy vegetation. In fact, they avoid the dense forest interior, although they can frequently be seen for example in clearings, in the undergrowth along streams or even in the

canopy. But guans and curassows are largely restricted to dense, humid forests, although some species occur, at least locally or seasonally, in more open forests, and others show preference for gallery forest. Also, from time to time, many guans venture into open areas near the forest, for example to visit a fruiting tree, especially in the dim light of morning or evening; this is much less frequent in curassows.

The types of forest inhabited by cracids are quite diverse. While chachalacas do not occur in unbroken humid forests, they are found in dry deciduous or semi-deciduous woodland, swamp and gallery forest and savanna, preferably in areas of contact with forest. They are also at home in secondary forest, plantations, especially of palms, brushland and thickets. Various species also occur locally in mangroves, and the race *deschauenseei* of the Plain Chachalaca, endemic to Utila Island, off northern Honduras, is actually now restricted to mangroves. Chachalacas are not particularly averse to cultivated or humanized areas, and are sometimes more abundant on the outskirts of small villages than in more remote areas.

Guans are restricted to the interior or margins of forests, mainly lowland rain forest, or, in mountain species, cloud forest. Often, the latter species prefer areas with an abundance of epiphytes, mosses and lianes. Some species are also present in tall second growth, especially where this is adjacent to primary forest, including swamp and gallery forest, and they can even turn up occasionally in coffee plantations. Several species of piping-guan are known to favour gallery forest, and the Black-fronted Piping-guan is normally associated with forests rich in palmito (*Euterpe edulis*), as its fruits form the bulk of the species' diet. In general, guans are not keen on drier forests, as is often apparent in the hills or mountains of Central America. In fact, in many areas where there is rain forest on the wet slope, and pine or pine and oak forest on the dry slope, guans and curassows are only present on the former. Locally, or seasonally, they can be found in drier habitats, as in the Crested Guan in west Mexico, which has been seen in oak-sweetgum and beech forest in Tamaulipas, and in humid pine-oak forest in Colima. The White-winged Guan is a special case with its present habitat of dry deciduous forest, although it seems to prefer the most humid parts, especially during the dry season. At the time of its discovery in 1876, this species also inhabited coastal fringe forest, and also islands in the delta of the Tumbes River with trees characteristic of dry forest, but densely fringed with mangroves. It seems that the species spent the hottest hours of the day in the dense mangroves, entering the dry forest at dawn and in the evening in order to feed.

The curassows are more strictly confined to rain forest than any other cracid group, and in many species there is a certain association with water, with a preference for flooded forests, borders of lakes and pools, or areas near rivers and streams. Some species also have a predilection for gallery forest, and it is in this habitat, in the *llanos* of Venezuela and Colombia, that the Yellow-knobbed Curassow is most common. The habitat of the only mountain curassows, the Southern and, especially, the Northern Helmeted Curassows, consists of cooler highland forests, with the latter preferring areas of very dense cloud forest. Curassows are even more reluctant than guans to enter dry forest. The Great Curassow, for example, is absent from the dry forests of west Mexico in which the Crested Guan occurs, and this appears to be the curassow least restricted to rain, cloud or gallery forest, as it is also found in seasonally drier forest in Yucatán and parts of Costa Rica, and even in scrubby woodland, in the case of the race *griscomi*, endemic to the island of Cozumel.

The altitudinal range occupied by the Cracidae is very wide. The widest diversity is in tropical lowlands, but several species live in mountains in subtropical and temperate zones. This is especially true of the guans, of which several species have morphological adaptations to help the birds tolerate these cold areas (see Morphological Aspects). The Andean Guan has been observed higher than any other cracid, at 3900 m in Peru, very close to the tree-line, but the Bearded, Red-faced, Wattled, Black, Sickie-winged, Highland and Horned Guans are also found in montane forest, often above 2500 m. In contrast,

The brightly coloured dewlaps that are found in all of the typical guans are believed to have a function in the maintenance of the pair-bond, and to play a role in courtship displays. Another characteristic common to the members of Penelope is the crest, formed by elongated crown feathers, which may be erected when the bird is excited. This feature is particularly pronounced in the Crested Guan, as its vernacular name suggests.

[*Penelope purpurascens*.
Photo: Rod Williams/
Bruce Coleman]

The curassows are undoubtedly the most highly evolved members of the family. Whereas in the guans functions of sexual recognition are attributed to the dewlaps, in the curassows these functions are performed by a very varied range of colourful appendages which decorate the heads of males, or, in some species, of both sexes.

The members of *Crax* have brilliantly coloured wattles and knobs, which start from the cere at the base of the bill, and vary with the species from yellow to orange, red or blue; again depending on the species, these adornments can be present only or mainly on the upper mandible, on the lower mandible, on both, or even, in one species, not at all. The

Yellow-knobbed, Blue-billed and Wattled Curassows give an idea of this rich variety. In the genus *Mitu*, the bright red bill itself has been modified, to a greater or lesser extent according to the species. The largest is the massive bill of the Razor-billed Curassow, which is entirely covered by the horny

ramphotheca. The two species of *Pauxi* have a large, raised, bony "helmet" on the forehead. The shape of the helmet, swollen and fig-shaped in the Northern Helmeted Curassow, more cylindrical and horn-shaped in the Southern Helmeted Curassow, is one of the main differences between the two species. Another is the crest formed of very short, tightly curled feathers, which, as is clearly visible here, is present in the southern species and lacking in the northern one.

The habitat of the West Mexican Chachalaca essentially consists of deciduous tropical forests, palm plantations and thick mangroves. The species does not occur in the most humid forest types, notably rain or cloud forest. In general, chachalacas are distinguished by their use of more open habitats, and they tend to avoid the interior of the dense, humid forests that form the principal habitat of the guans and curassows, although they may occur in forest edge and in clearings, or along streams and rivers.

[*Ortalis poliocephala*,
Chamela, Mexico.
Photo: X. Ferrer
& A. de Sostoa]

chachalacas and curassows are much more restricted to the lowlands, with the exception of the Northern Helmeted Curassow, which has been recorded at 2200 m. Nevertheless, some lowland species can be found at considerably higher altitudes in certain areas. The Great Curassow, generally a lowland bird, has been found at 1900 m in the Chiriqui Mountains of Panama. The same happens in some chachalacas, for instance the Speckled Chachalaca, which occurs at sea-level, but has also been observed at 2500 m in Colombia. Again, the West Mexican Chachalaca in the southern tip of its range manages to occupy fairly humid areas up to 3000 m. This last case refers to the area where the species overlaps with the Plain Chachalaca, a bird of drier habitats, and in this contact area the latter's preference seems to be even more accentuated. This appears to be a case of ecological segregation, which avoids or reduces competition between morphologically very similar species (see Systematics). A similar situation seems to arise in areas where two species of *Penelope* coincide. For instance, in south-east Venezuela, where Spix's and the Marail Guans coincide, the latter appears to be restricted to the forest interior, while the former is often seen at the forest edge, in clearings with scattered trees and in gallery forest. The remarkable size difference between these congeners probably helps to reduce competition, as it promotes the exploitation of different resources. Logically, such competition is much reduced or disappears between species of different genera, in which important adaptive differences have developed. In Vaupés, Colombia, the Nocturnal, Black and Crestless Curassows (*Mitu tomentosa*) and Spix's Guan can coincide in the same forest.

General Habits

The behaviour of cracids is generally not well known, because most species live in forests, often in the most inaccessible areas, and they inhabit the Neotropical Region, where very few detailed studies have been carried out. In addition, much of the information that has been regularly reiterated about the family comes from early South American explorers, many of whom based their accounts on rumours and legends of the local

people. Because they inhabit more open areas, frequently near settlements, and are thus much easier to observe, the chachalacas are generally the best known group.

Cracids tend to be fairly gregarious. Although it is not rare to find a lone bird, cracids are more often found in pairs or small family groups. Sometimes more numerous groups form, especially in chachalacas, which tend to be the most sociable group in the family, particularly outwith the breeding season. Thus, in several chachalaca species, groups of 20-30 birds may feed together; or even up to 50 Rufous-vented Chachalacas in the *llanos* of Venezuela. There is also an old record of a flock of more than 50 Crested Guans in the same fruit tree in Yucatán. Similarly, in various species of piping-guan, flocks of 10-20 are often sighted, in the past even of species that are now endangered, like the Trinidad and Black-fronted Piping-guans. Large flocks normally gather where food is abundant, typically in fruiting trees that also attract many other bird species. After feeding, the birds leave the tree and the group splits up again into smaller units, generally pairs or females accompanied by a few young, the most typical social units in this family. Similar congregations occur at water-holes or other drinking sites, during droughts. Loose aggregations of up to 50 or occasionally 100 or more Yellow-knobbed Curassows used to occur in the dry season in the *llanos* of Venezuela, and smaller concentrations can still be found.

Single-sex flocks have been seen outside the breeding season on several occasions, with up to eleven Bare-faced Curassow males together. The record of a group of four male Red-billed Curassows at the beginning of the breeding season could refer to birds that had failed to establish territories.

Cracids are mostly diurnal, but singing and displays often take place in the dark. The characteristic wing-drumming flight displays of the guans are performed very early in the morning, when it is still so dark in the forest that it is difficult to imagine how they can see their way from perch to perch. The same time, about an hour before sunrise, is equally the peak moment for singing in curassows, but unlike the guans' wing-drumming displays, these can also be heard during the day, and they often continue into the first hours of darkness after sunset, or can even be heard in the middle of the night when the moon is full.

The curassows are typical inhabitants of the humid Neotropical forests. Some species prefer permanently or seasonally flooded forests, while others seem more closely tied to terra firme or other forest types, and the two species of Pauxi live in cloud or montane forest. Gallery forest is also used by some species, such as the Bare-faced Curassow, particularly in the Pantanal, an immense flooded zone in south-west Brazil which is particularly rich in this habitat type. The Yellow-knobbed Curassow (*Crax daubentonii*), present in an area of rather similar characteristics, the llanos of Venezuela and Colombia, is commoner in gallery forests than in any other habitat.

[*Crax fasciolata fasciolata*,
Pantanal,
Mato Grosso, Brazil.
Photo: Eric Soder/NHPA]

Nocturnal feeding has also been recorded. The Trinidad Piping-guan typically feeds in the late evening, but it usually continues foraging until one or two hours after nightfall, after which time the sound of fruit falling to the ground ceases abruptly. The Southern Helmeted Curassow has been seen feeding on moonlit nights, and is especially active on the days that follow moonless nights.

The case of the Nocturnal Curassow is exceptional. Unlike the other species, it sings only in hours of complete darkness, even when there is no moon; it is never heard during the day, not even at dawn or dusk. Because of this and the explanations of early naturalists, who heeded native reports that the bird spent the day sleeping in a hole at the base of a tree or between rocks, for a long time the species was believed totally nocturnal. Vaurie found that the orbits were proportionally larger than in the other species, even though live birds do not appear to have particularly large eyes. Nevertheless, when the species was first kept in captivity, it was noted that although the birds did indeed sing at night, they spent this time on a high perch hardly moving at all; in contrast, they were active on the ground in their enclosure during the day, when they ate the food that was provided. It was also argued then that their vegetarian diet would make it difficult for them to find their food in the dark, unlike the owls, nightjars and other nocturnal birds that eat animal food. For this reason, they are now believed to be diurnal, or at least partially so, perhaps feeding around dawn and dusk. Their nocturnal activity may even be limited to the territorial singing of males. However, conditions in captivity are obviously not the same as those in the wild, and until adequate field studies are carried out, the possibility remains that they are partially nocturnal. Another possible indication of nocturnal habits is the fact that they can often be heard in areas where heavy hunting pressure has practically eliminated all other curassows.

Most cracids follow a fairly similar daily routine. The White-winged Guan, for example, begins its activities at about 5:45 hours, before dawn, when it performs the early morning flight displays found in almost all guans; although these displays are mainly related to breeding (see Breeding), in many species they also take place outside the breeding season, at least

sporadically. A little later, the birds go down to the bottom of the valley to drink and feed until 7:30 or 8:00 hours, or even on occasions until 10:00 hours. They spend the hottest hours of the day in a cool, shady place where they rest and continue feeding, with very little movement, until they become active again between roughly 16:30 and 18:45 hours. After this, they look for somewhere to roost, generally well hidden in a tree at medium height, and here they pass the night. Often the roosting site varies from one day to the next, at any rate in the Crested Guan, when it has been observed several days in succession. This species normally wanders about all over its territory from day to day, only occasionally staying in roughly the same place two days running. On the other hand, other species, especially chachalacas, have been seen flying every evening to the same large tree, apparently to roost, which suggests that they probably roost communally. There is also a record of three Grey-headed Chachalacas roosting in close physical contact on a wire, and in roosting groups of this same species two birds were seen billing, as parrots do, although only for a few moments.

Activities carried out during the hours of rest include dust-bathing, sunning and preening. The Plain Chachalaca has been seen dust-bathing on paths and in cornfields, while three adjacent dust-baths of the Rufous-vented Chachalaca were found in the only suitable site with soft, dusty soil in an area of the Venezuelan llanos. These activities are important for removing parasites, keeping the feathers in good condition and keeping the plumage well oiled, but in some cracids they have the additional function of strengthening the pair-bond during courtship. Thus, the male Horned Guan often calls its females to the dust-bath, a gap in the forest caused by a treefall, where the sun reaches the forest floor and dries the soil. After both birds have bathed, the male usually feeds the female with green leaves; apparently, the nest-site is later chosen nearby. Similarly, in the Yellow-knobbed Curassow, apparently a polygynous species, like the Horned Guan (see Breeding), males have been seen courting one or even two females simultaneously at the dust-bath.

Preening is an activity to which cracids dedicate a considerable amount of time. One of the very few studies of cracid

behaviour, that by F. González-García on the Horned Guan in Chiapas, Mexico, showed that this species devoted more time to plumage care and cleaning than to any other activity, including feeding. Preening was performed in a tree, with the bird sitting or standing, and generally devoting most time to the feathers of the back and wings. After a preening session, the bird sometimes exposed its plumage to the sun, possibly in order to remove ectoparasites or to dry itself. Similarly, the Plain Chachalaca has been seen sunning, with wings and tail spread, in sunny spots on roads, while similar behaviour has been recorded in the Black Curassow, in small clearings or on roads. The Red-billed Curassow has been seen coming out onto tracks after rain, in order to dry and preen.

There are also stereotyped false preening movements, with the head thrown back over the shoulders and wings, but without the bill touching the feathers; they are normal in cracids and may indicate anxiety. Other common habits include flicking the tail feathers open and then shut, and quick, sideways flicks of the head. The latter could be a defence mechanism against insects that host parasitic nematode worms which sometimes afflict cracids' eyes, although in the Great and Salvin's Curassows (*Mitu salvini*), they have also been observed in relation to courtship feeding.

Voice

Cracids are highly vocal birds with a remarkable repertoire of songs and calls, some of which are very loud, such as the cries of chachalacas or the crowing of Spix's Guan that can be heard from a kilometre or more, depending on local topography. In many species the trachea is elongated, sometimes considerably, a modification that increases the loudness, especially of the low-pitched notes that are typical of many of their vocalizations (see Morphological Aspects). Nevertheless, vocal characteristics vary markedly among the different natural groups.

The songs of all chachalacas are similar, with one exception. They are loud cries, often emitted as well co-ordinated rhythmic duets by the members of a pair, or by more birds,

creating a strident, reverberating chorus, in which not only can the voices of individuals be distinguished but also those of pairs singing in duet. Often, the calling of a pair or a flock stimulates other birds to join in, filling the forest with an almost continuous "chachalaca chorus" which can last more than two hours, generally early in the morning. Indeed, the name "chachalaca" comes from the sound that the birds produce, as do many other local names, like Guacharaca, Charata or Wakago. Despite their resemblance, the calls of the different species are not identical, and this may be an important isolating mechanism. In support of this, the differences are more marked between species with partially sympatric ranges, as in Chiapas, southern Mexico, where the ranges of the Plain, West Mexican and White-bellied Chachalacas meet.

The single exception is the Grey-headed Chachalaca, as it does not produce the loud chorus characteristic of the other species. It makes quite different notes from those of the others, and never engages in the strident group calls. It is, however, a noisy bird too, and it emits a variety of mainly loud, harsh cries, although these do not follow any set pattern or rhythm.

Apart from their songs, all chachalacas have other calls, including squawks, whistles or clucking; these are made from time to time or repeatedly in different circumstances. Birds often make such sounds while feeding, which probably helps the pair or the group to stay together. Again, they may be used when birds come across other conspecifics alien to the group, and this can be followed by a confrontation. They are also used as an alarm call in the face of predators or man.

Guans are also noisy birds that produce diverse vocalizations, described as grunts, growls, cackles, yelps and crows, and which have been associated with courtship, mating, pair-bond and flock integrity, territorial confrontation and alarm. The discordant crowing of Spix's Guan, which mainly consists of hoarse notes, has been referred to as one of the loudest and most far-reaching sounds of any bird. However, the most characteristic display sounds of the guans are not vocal, but mechanical, namely the wing-drumming displays (see Breeding) for which the wings show special modifications (see Morphological Aspects). These sounds are often accompanied by vocalizations, either just beforehand or simultaneously, which might indicate that both serve the same purpose, at any rate to some extent. However, evidence suggests that calls have more of a territorial function, while wing-drumming is more related to courtship. In addition, some guans produce very characteristic songs, such as the loud siren or ring of the male Wattled Guan, to which it owes its generic name, *Aburria*. Other examples include the piping, a series of five or six clear

Sunbathing is one of the activities recorded amongst cracids during periods of rest. Sometimes the birds will sunbathe in trees, like this Band-tailed Guan, which is stretching its wing wide open to soak up the sun, but at any rate chachalacas and curassows will also sunbathe on the ground, for example in a clearing or in the middle of a road. One of the most obvious functions of sunbathing is to dry the feathers when they are wet, but it is also believed to be useful for removing ectoparasites.

A captive Salvin's Curassow preening. Care and cleaning of the plumage is one of the activities to which cracids devote most time. The feathers of the back and wings are apparently those which receive most attention.

[*Mitu salvini*. Photo: Josep del Hoyo/Lynx]

The daily routine of the Rufous-vented Chachalaca is similar to that of nearly all the other species of cracids. Most feeding takes place during the first and last hours of the day, while most of the rest of the day is spent resting and in comfort activities, such as preening, dust-bathing and sunning. The chestnut tail tips of these two birds show that they are members of the nominate race, which occurs on Tobago. This is the only species of cracid on the island, and has officially been named Tobago's National Bird.

[*Ortalis ruficauda*

 Planet Earth]

whistles gradually ascending in pitch, that has given rise to the common name of the piping-guans, and the loud, clear, human-like whistles of the Highland Guan, uttered with the bill wide open. However, in *Penelope* and probably also *Chamaepetes* there are no real songs, except perhaps in the Band-tailed Guan, which sometimes makes calls similar to the piping of piping-guans. The absence of true song in many guans may result from its substitution by wing-drumming, although some of the most specialized drummers, like the piping-guans, both sing and drum.

The Horned Guan is unusual amongst guans in terms of voice. It makes a mooing song composed of three or four soft, deep notes that are repeated with marked regularity several times a minute. The sound is noticeably ventriloquial, giving a false impression of the bird's whereabouts, and is quite similar to the typical song of curassows. This is one of the reasons why the species is sometimes considered to be half way between the guans and the curassows (see Systematics). It also produces a sound unique amongst cracids, by clacking its mandibles together repeatedly for a few seconds, probably in alarm.

Curassows have a very different song from those of the chachalacas and guans, except to some extent the Horned Guan. In most species the sound is a low-pitched ventriloquial booming, which is difficult to locate, and which never sounds loud even in close proximity to the singing bird. The sound is like that made by blowing across the mouth of an empty bottle. Booming lasts 5-7 seconds and is emitted at intervals of roughly 12 seconds for about half an hour, normally in the early morning or the evening, but sometimes during nights with a full moon, and occasionally, for shorter periods, at any hour of the day. In captivity it has been seen that when the bird booms, the bill remains closed, implying that the sound may be, at least partly, non-vocal in origin; thus, the "oomh" might be the result of a powerful expulsion of air from the throat. In support of this, some males captured during the courtship period had the skin of the neck richly vascularized, perhaps to prevent it stretching when it is distended by the accumulated air.

Apparently only male curassows boom, but females can make low-pitched notes, for instance those emitted repeatedly by pairs in order to maintain contact while walking through the

forest. Differences in song pattern could also act as isolating mechanisms to help prevent hybridization when the ranges of two booming curassows overlap, as is probably the case among chachalacas.

Curiously, the Yellow-knobbed and Wattled Curassows, members of a superspecies that contains some of the most typical boomers, have a completely different song. Instead of booming, the males' song consists of a long, leisurely whistle. More emphatic whistles are also made by some of the other species, for instance the Great Curassow, not as songs, but rather as signs of irritation or alarm.

In general, cracids' songs are associated with the breeding season, although singing can go on to varying degrees throughout the year. At least in the majority of species, the song clearly has a territorial function, as much to attract a mate as to warn off rival males, and very probably also to reinforce the pair-bond, or the cohesion of a group in the more social species.

The chicks and half-grown young of several species, when wandering along in the company of adults, make soft piping sounds from time to time that enable them to be located rapidly, although this can betray their presence to predators. In such flocks, the adults also tend to repeat warning cries of low or medium intensity, in order to prevent the most vulnerable young from straying.

Food and Feeding

The cracids are essentially vegetarian. Although detailed studies on feeding have only been carried out on a few species, and the data available on the rest come from very limited field observations or the stomach content of collected specimens, it seems that they take animal prey only occasionally. In such cases, prey includes fair sized insects, like grasshoppers, beetles or caterpillars, or other invertebrates, like spiders, centipedes and some molluscs, although exceptionally vertebrates have been recorded, including salamanders, caecilians, tree frogs and small rodents. The Razor-billed Curassow has also been seen taking ants and termites in an opportunistic manner, after coming on their columns, while foraging for fruits and seeds as

These three Plain Chachalacas huddled together demonstrate a form of behaviour that is not unusual amongst the chachalacas, and, in fact, it often results in full bodily contact. This behaviour, together with some observations which indicate the possible existence of communal roosting sites, suggests that the chachalacas are the most sociable of the cracids.

[*Ortalis vetula*.

FLPA]

usual. Also, when curassows first offer food to their chicks, this often includes invertebrates, such as insect larvae and termites.

The plant matter that constitutes the bulk of the diet includes fruits of all types, seeds, flowers, buds, twigs, shoots and leaves. Leaves are usually eaten by the chachalacas and various species of guan in considerable quantities, and not only those that are sprouting or are still very tender, as typically consumed by several other groups of birds, but also much coarser ones, that are otherwise frequently eaten only by the Hoatzin (*Opisthocomus hoazin*). Leaves are sometimes swallowed whole, but often, at least in chachalacas, bits are plucked off a leaf that is still attached to a twig. Whole flowers may be taken or sometimes only the petals, depending on the plant species. Large fruits like mangoes and guavas are pecked at, while berries and other smaller fruits are swallowed whole one by one. Sometimes, after swallowing a fruit whole and taking the pulp into the crop or the gullet, a bird regurgitates the hard, indigestible seeds, as is the case of the Black-fronted Piping-guan with certain palm fruits. In other cases, fruit stones pass through the digestive tract whole and are then defecated.

In contrast, curassows have a powerful, muscular gizzard with a rough lining, which can easily crush nuts and hard seeds of up to 2 cm in diameter, and such food forms an important part of their diet. Some fairly large guans also have quite muscular gizzards, which have thinner walls than those of curassows, but which are capable of grinding down acorns, a typical food in the diet of the Crested Guan; they can also deal with the hard or unripe fruits, including palm fruit, that are often consumed by the piping-guans. The smaller species of guans, though, have to feed on softer fruits, shoots and green leaves. In an area in the south of Mexico where the Great Curassow, the Crested Guan and the Plain Chachalaca coincide, the berries of the hackberry (*Celtis laevigata*) form part of the diet of the three species, but the last two digest only the pulp that encloses the seeds, while the curassow, with its more powerful gizzard, is capable of crushing and therefore assimilating the seeds too.

This disparity in the ability to digest seeds implies different relationships between these birds, which are basically or partially frugivorous, and the plants on which they feed. The

species that regurgitate or defecate the seeds whole play an important role in the dispersion of some plants, but it has been suggested that the species that destroy the seeds with their gizzards also exercise a positive effect on the plant. This process favours the scattered seedlings that do indeed sprout, by reducing competition between them and perhaps also preventing the propagation of parasites.

In general, each cracid species consumes a remarkable diversity of plant species, with one or other predominating, or varying in comparative importance throughout the year, depending on when each sprouts or flowers, or when the fruit ripens. Recent studies of several cracids have identified a fair number of food plants, for instance 43 for the White-winged Guan in northern Peru, 68 for the Razor-billed Curassow in Peru, and 80 for the Black Curassow in French Guiana. It has recently been suggested that the diversity of the diet, in terms of both the species and the parts of the plants consumed, is modified with the season. The diet is more varied during the dry season or during the transition from the dry to the wet season, because food is scarcer, and above all because fruit production is minimal. In the rainy season, the time of maximum abundance, the bird's ecological niche is narrower, not only with fewer species consumed but also with food being selected more carefully.

Recently, M. Théry, C. Énard and D. Sabatier, who had already studied the diet of the Black Curassow and other frugivorous birds in French Guiana, investigated the feeding habits of the Marail Guan, which were completely unknown until then. They found that this species was highly selective. The fruits of only four plant species constituted 75% of the diet, with only 24 plants identified in all, half of which contributed less than 1% in total. The species is almost completely frugivorous, depending almost entirely on fruit even in the dry season, when other species increase the proportion of flowers and other plant elements in their diets. This tendency might be related to security against potential predators, which are numerous for this species because of its small size. Birds feed at a few particular sites, where their main food species abound, moving quickly and directly between these areas and resting places, without feeding on the way. The Black Curassow, in contrast, with a smaller range of potential predators due to its

larger size, feeds on fallen fruit, as it moves along more slowly over less fixed routes.

In some cracids, a certain type of food can dominate quantitatively, at least in part of the range, although this phenomenon is not common. It is the case of the Black-fronted Piping-guan, which is particularly keen on the fruit of the palmito, in search of which it will move long distances (see Movements).

Occasionally, chachalacas and some guans visit cultivation in order to feed. They sometimes eat shoots of maize, beans and sweet potatoes, and also coffee beans. In the case of the Dusky-legged Guan, birds have been known to invade poultry yards to feed on corn. However, such occurrences are sufficiently infrequent that they are not usually considered a nuisance to man.

All cracids can store food before beginning to digest it, and, although only the curassows have a true crop, the oesophagus of the guans and chachalacas is greatly expandable and serves the same purpose. First the stomach is emptied and then the next batch of food enters from the crop or the gullet.

The various food items are taken with the bill from trees and shrubs, at any height, or from the ground, where fallen fruit, various kinds of seed and sometimes insects or other invertebrates can also be found. The curassows generally feed on the ground, while guans are predominantly arboreal, although sometimes they too feed on the ground, especially taking fallen fruit after visits by groups of monkeys, parrots, toucans or other birds. The chachalacas are more terrestrial in their feeding than most guans, but they often take their food directly off the vegetation. On the ground, cracids occasionally scratch with their feet to uncover food, but much less frequently than in other gallinaceous birds, such as junglefowl (*Gallus*) and their domestic descendants.

Many cracids, especially the curassows, often swallow small pebbles, which help them to grind up hard food in the gizzard. Several species visit salt-licks to take in salty earth; they also visit certain areas in order to ingest clay-like soil, which probably responds to the necessity of adding mineral supplements to their diets.

Cracids drink, especially during the dry season. They come down to the ground to drink from streams, rivers or ponds, sucking with the bill held under the water. They have also been seen taking water trapped in leaf bracts or in the flowers of forest epiphytes, or drinking from leaf tips as the drops fall after heavy rain.

Chachalacas and guans feed their chicks by regurgitating food which they then drop from the bill. With the bill tip, curassows sometimes offer food to their chicks, when these are very small, but unlike the other members of the family, they never regurgitate it. Cracid chicks show a great capacity for finding food from a very early age, although the adults often call them to indicate a particularly good food source. Even when they are fully-grown and capable of foraging by themselves, young birds still sometimes receive food from their parents.

Breeding

The breeding season varies with locality in the cracids. At the latitudinal extremes of the family's range, where there is a true spring, breeding tends to take place in this season. In the tropics, birds mostly breed during the wet season, although the breeding season is usually rather protracted; some species have no fixed breeding season, with birds laying almost at any time of year.

There are contradictory hypotheses about the reproductive strategy of the cracids. The guans and curassows were originally thought to be monogamous, whereas the more gregarious chachalacas were described as promiscuous and polygamous. However, Delacour and Amadon stated that all the cracids, except perhaps the Highland Guan, were actually monogamous. In support of this, most recent evidence on the chachalacas indicates that they form strong pair-bonds. The synchronized duet of the pair is performed more often when the pair is alone than when included in small flocks, and is typical of monogamous birds. Everything seems to indicate that, like other cracids, chachalacas are territorial, both members of the pair

Dust-bathing is a common activity amongst galliforms, and the cracids are no exception. This behaviour is better known in the Horned Guan than in any other member of the family, thanks to the studies carried out in El Triunfo Biosphere Reserve, in Mexico. The birds dust-bathe in treefall gaps, where the sun's rays reach the forest floor and dry the soil, and they normally do so once a day, between 12:00 and 16:00 hours. In addition to the well known functions of helping to keep the feathers in good condition and removing parasites, in this species dust-bathing appears to strengthen the pair-bond, as males have frequently been seen calling their females to the dust-bath during the courtship period.

Chachalacas are highly vocal birds which produce very loud calls and songs. The name "chachalaca" itself is onomatopoeic and refers not to the song of a single bird, but rather to the chorus produced when several birds sing together. Clearly visible in this singing West Mexican Chachalaca is the bright red bare throat, which must have similar sexual functions to the dewlaps of the guans, even though it does not dangle down in the same way. In this species, the bare orbital skin is also red, thus adding to the eye-catching effect.

& A. de Sostoa]

normally defending the territory and confronting intruders. Chachalacas can be quite aggressive and conflicts can easily lead to fighting. Incubating females of the Rufous-vented Chachalacas may even leave the nest momentarily, to help the male expel an intruder.

Nevertheless, there appear to be some exceptions. In Costa Rica, A. Skutch observed a Grey-headed Chachalaca nest, where the incubating bird was indifferent to the approach of groups of conspecifics. Over a period of several days a mate was never observed, whereas in other species, although the male does not incubate, its presence in the vicinity of the nest is obvious. Perhaps in this case the other partner had died, but it might be that this species follows a different breeding strategy; indeed, it is the only chachalaca not to make the characteristic "cha-cha-lac-a" call of this group (see Voice). On occasion, chachalacas breed in loose colonies, and three occupied nests of the White-bellied Chachalaca were found in adjacent trees; the occurrence of several empty nests of the Plain Chachalaca in a small area might suggest the same thing, although they might not have been used simultaneously.

Until recently guans and curassows were thought to be monogamous, over one or possibly even many seasons, although most of the information came from captive birds. However, recent fieldwork has shown that, while monogamy does seem to be the norm, there are more exceptions than was previously thought. It was already noticed some time ago that in some species of curassow males tend to be accompanied by two or three females, but this was attributed simply to possible higher mortality amongst males. As males are more easily located by their calls, they could be more vulnerable to hunting pressure, and might also suffer higher mortality due to natural causes, as happens in some other monogamous birds. One such species is the Yellow-knobbed Curassow, which regularly occurs in groups of up to 15 birds in the dry season. In the *llanos* of Venezuela, R. Buchholz noted that the male does not appear to defend feeding territories or care for the chicks. Males performed vocal displays within earshot of one another, from calling trees at the edge of gallery forest. Females spent most of their time in the forest, but visited these calling sites singly or in groups, and were courted by the resident male. This

suggests that the species is polygynous, one male mating with several females in the same breeding season.

Over a period of seven days, three different female Horned Guans were seen in one male's territory: one of them was alone, and copulated with the male; another was accompanied by a one-week old chick; and the other had two 15-day old chicks. Although the probable polygyny seems to be at least partially simultaneous in this case, serial polygyny would explain the variation in breeding dates for different females in this species.

In the Amboró National Park, Bolivia, G. G. Cox and R. O. Clarke recently studied the very poorly known Southern Helmeted Curassow. They found that at the beginning of the rains the population, until then dispersed, forms small groups which then assemble at a site deep in the forest where males emit their booming song at a lek. After mating, the females apparently go off to nest alone. This system differs from that followed by the closely related Northern Helmeted Curassow, which is usually seen in pairs or family groups throughout the year. It is apparently monogamous in the wild, although a probable case of bigamy, with two occupied nests 130 m apart in the same territory, indicates that a particular species may not always stick to the same breeding strategy.

Although poorly known in many species, courtship in cracids includes some very peculiar activities, such as the wing-drumming flights of the guans, and the sophisticated ceremonies that some curassows perform on the ground. The courtship displays of chachalacas generally seem to be simpler, and probably include strutting and calling with the head erect, mutual preening, pecking, rapid chases and courtship feeding, all of which seem to occur equally on the ground or in the tree tops.

The wing-drumming or wing-whirring displays of the guans are unique among cracids, and, as far as is known, do not take place in the markedly distinct Horned Guan. Although in some species they may be produced throughout the year, they are more frequent during the breeding season and in some species are limited to this time, showing that they are clearly related to breeding. They are performed very early in the morning, when it is still dark in the forest, making detailed study difficult.

The chorus of the Rufous-vented Chachalaca can be heard on most mornings during the breeding season. It starts after sunrise, often an hour or two afterwards, and is kept up almost without interruption for at least half an hour, and sometimes for over two hours. Once the chorus has finished, normally between 09:30 and 10:30, there may be further short outbursts, normally of less than five minutes, at any time of day, and on occasions there is another relatively lengthy session in the late afternoon. The song and calls of the male of this species are lower-pitched than those of the female, and with experience it is possible to distinguish the sexes by voice.

[*Ortalis ruficauda*.

Bruce Coleman]

This Spix's Guan was photographed at a salt lick which is also frequently attended by other birds and some mammals. Various species in this family have been seen ingesting a particular kind of clayey soil that is to be found only in particular places. It seems that, like many parrots, some cracids add a mineral supplement to their diet.

[*Penelope jacquacu jacquacu*, Peru.
Photo: Günter Ziesler]

This display is carried out during a special flight. In general, the bird flies off its perch in a tall, emergent tree, glides in the open for about two seconds, and produces the wing-whir for about three seconds by beating the wings twice as fast as in normal flight; it then glides on to another, similar perch, generally lower down. These flights are usually over a distance of 50-175 m, although on abandoning the display area, a bird sometimes drums and continues to fly for longer distances. Sonagrams have shown that the wing-whir itself is divided into two portions separated by a pause of less than half a second. In the first part the wingbeats speed up, but at the end of the second they slow down again. The same individual usually makes its display several times in the same session, using different perches each time.

There are slight differences in the display between different species of *Penelope*; for instance some whistle just before drumming. In the piping-guans the display is similar, but at the moment of take-off they make one or two loud wing-claps, after which they immediately wing-whir. Another difference in this group is that the first portion, before the pause, is longer than the second, the opposite of what happens in *Penelope*. In addition, the more elaborate modification of their outer primaries (see Morphological Aspects), and the fact that their wingbeats are faster, makes the sound much sharper and drier. So, if wing-drumming in *Penelope* recalls a series of dull thumps, or the ruffling of a drum, the wing-whirring of *Pipile* is like the sound produced by ripping a piece of thick cloth. The latter also carries further, and can sometimes be heard more than a kilometre away. While flight displays stop before dawn in *Penelope*, they can carry on into the morning and even in full daylight in *Pipile*. All species occasionally drum at unusual hours, for example on an overcast day or in the middle of a moonlit night.

Wing-drumming displays are used to maintain the pair-bond and perhaps also to help in pair formation. If there is any territorial function, it seems to be secondary. In the Crested Guan the display seems to be performed by the male only, although in the presence of his mate, and the same may occur in other species. It should be noted, however, that the modifications of the wing quills are present in both sexes.

The curassows perform fairly elaborate displays on the ground, although the Yellow-knobbed Curassow has been seen flapping its wings loudly and repeatedly, while it whistles its song from a tree top. The most elaborate display recorded in the wild is that of the Black Curassow, described by W. Beebe at the beginning of the century. The bird, almost certainly a male, adopted a spectacular posture while it walked slowly through a clearing in the forest in front of two other birds, possibly females. The presumed male leaned forward with its breast very low and the bends of the wings drooped downwards. The head and the tail were raised, with the tail pointing straight up and the white of the abdomen and undertail-coverts noticeably fluffed out, contrasting with the otherwise black plumage. From time to time, the bird stopped to pick up a pebble and hit its head violently against its back, with a clicking sound. Immediately afterwards, it dropped the pebble and clapped its wings seven or eight times. After several convulsive movements, it adopted a half-squatting posture, with the head and the tail low, and made a booming call. The bird observed by Beebe repeated the display in every detail five times in twelve minutes.

Information on the displays of other curassow species comes mainly from captivity. The Great and Red-billed Curassows perform displays quite similar to those of the Black Curassow, but somewhat simpler. A male Blue-billed Curassow repeatedly caught and threw pebbles, and male Wattled and Northern Helmeted Curassows will trot in circles round females. Courtship feeding has been recorded in the Nocturnal, Salvin's, the Great and the Bare-faced Curassows. The fact that none of the displays described for other species is as complex as that of the Black Curassow may be due to insufficient observations or because courting is inhibited in captivity, but it may also be related to the reduced sexual dimorphism in this species, the least marked in any species of *Crax*.

In curassows and chachalacas copulation usually takes place on the ground, although Chaco Chachalacas (*Ortalis canicollis*) have been seen copulating in tree tops, and this may also happen in the most arboreal guans. Male cracids have a penis-like organ.

In the curassows, courtship normally takes place on the ground and may include quite sophisticated ceremonies, involving a series of movements which are normally performed in a regular sequence, with none of the constituent parts omitted. Wing-flapping is one of the most frequently recorded actions, and, as illustrated by this male Bare-faced Curassow, it helps to highlight the contrast between the generally black plumage and the white lower abdomen, which in normal conditions is very inconspicuous. Courtship feeding has also been observed in various curassow species. The male picks up a food item and then turns his head to one side and waits, sometimes for some considerable time, until the female comes and takes the food from his bill.

Cracid nests are nearly always built in the vegetation, and there are very few documented records of nests built directly on the ground. The Plain Chachalaca's nest is a rather flimsy structure built of broken off sticks and twigs. Green leaves are often used for lining the inside of the nest, and they are also typically incorporated into the main nest structure itself. The nest is small in relation to the size of the bird, as is the norm in this family.

[*Ortalis vetula vetula*, Chiapas, Mexico. Photo: X. Ferrer & A. de Sostoa]

Both members of the pair participate in nest building, although in some species the male may do most of the work. In captivity, the nest is sometimes built by the male only, but this has been interpreted as a sign that the female was not in breeding condition. In contrast, some of the few nests known of the Northern and the Southern Helmeted Curassows were apparently constructed entirely by females.

The nest is almost always situated in vegetation, in a tree, shrub or vine, in some cases up to 20 metres above the forest floor, but usually quite a lot lower. Often the nest rests solidly on the top of a broken snag, on an accumulation of dead leaves in a large fork, on a thick palm frond, on the leaves of a bromeliad, on an arboreal termite nest, or even on one of the birds' old nests. There are many old reports of nests being built directly on the ground, but most are now considered dubious, and the habit has only been confirmed for the Highland Guan and the Rufous-vented Chachalaca. In the latter, two out of six nests were on the ground. In the former, the first nest found was on the ground under a log, from which it was deduced that this was the norm for the species. Later, of 16 nests found at one site only one was on the ground, and it had been deserted. Both the Rusty-margined Guan and the Black-fronted Piping-guan occasionally nest on large rocks in the forest.

The nest is usually in the form of a flat dish and is small in proportion to the size of the birds, especially when it is built on a solid base, such as a stump, in which case it is flimsy and misshapen. It is loosely built from sticks, twigs, creepers and other coarse materials, especially varied in the chachalacas which also tend to include grass stems tucked in at the sides. Often nests also contain green leaves, sometimes many, which make the structure more compact when they dry off. The cup is sometimes lined with fresh vegetation.

The eggs, generally laid on alternate days, are white or cream coloured, and are not marked at all, although they are sometimes strongly stained by the green vegetation on which they rest, particularly in wet weather. Their surface is pitted, strongly in the curassows and somewhat less in the chachalacas, but it is smooth in some guans. However, there are sometimes

marked differences between different clutches of the same species, or even between different eggs of the same clutch. Eggs are large in proportion to the size of the bird, although the differences between the several groups are considerable: while the average egg size of the Great Curassow is 92 x 67 mm, that of the Plain Chachalaca is 58 x 41 mm. Clutch size is small, in contrast to the more typical Galliformes. Curassows usually lay two eggs, while chachalacas and guans usually lay three, or occasionally four. Clutches of only one egg have been recorded in curassows, and of only two in chachalacas and guans, but some of these clutches may have been incomplete. A Plain Chachalaca nest found in Texas containing nine eggs was undoubtedly the result of several females laying in the same nest.

There is insufficient information available to establish whether or not cracids lay replacement clutches in the wild. They probably do, as in captivity they manage to lay four or more in a season, if the eggs are regularly removed. Without interference, some species, such as the Dusky-legged Guan, can lay two clutches annually.

Incubation is carried out by the female alone. During this period, the male Rufous-vented Chachalaca often remains watchful in the vicinity of the nest, but rarely actually in the nesting tree, except when it is necessary to expel an intruder. The female sometimes leaves the nest during the day, in order to feed, often in the company of the male. In the same species this occurs three or four times a day, five at the most; she is normally absent for slightly over an hour, seldom more than two, and clearly for shorter spells than her incubation stints, which often last more than three hours. If it begins to rain while the female is away, she quickly returns to protect the eggs from the rain. A female Horned Guan left her nest three times a day, in the morning, the middle of the day and the afternoon, and another did so four times, but less as hatching approached, perhaps partly due to the heavy rain that happened to fall on those particular days. A female Northern Helmeted Curassow did not leave her nest more than once a day, generally in the morning for one to two and a half hours; on very rainy days

One of the differences between cracids and other galliforms is their small clutch, which normally consists of two eggs in the larger species and a maximum of four in the chachalacas. The eggs are relatively large, and are white or cream-coloured without any kind of pattern. Incubation is performed exclusively by the female, and in the case of the Horned Guan lasts between 34 and 36 days, one of the longest incubation periods of any cracid. The nest of this species, built high up a tree, is rather rudimentary, and is small in comparison with the size of the bird.

she would not leave the nest at all. Sometimes incubating females will add some material to the nest. During the hottest hours the incubating bird tends to pant actively in order to dissipate heat, and she often preens while sitting on the eggs. Incubation lasts about 24 days in chachalacas, 28 in guans, and normally 29-32 in curassows, with some variation between species; for instance in the Northern Helmeted Curassow it can exceed 34 days.

The chicks are relatively large and robust, so hatching is fairly rapid, apparently without the resting periods that typically occur in other birds. In captivity, it has been noted that after a curassow chick pips the egg it takes no more than two or three hours to emerge totally. At two nests watched in the wild, one each of the Grey-headed Chachalaca and the Horned Guan, the process was virtually simultaneous, with all of the eggs hatching within the space of one or two hours. Synchronous hatching has also been confirmed in the Plain Chachalaca. Chicks are covered in down with a variegated pattern, mainly pale brown and black, that serves well as camouflage. The down is heavy and dense, especially in mountain species, and the quills of the primaries and secondaries have already sprouted at hatching. Chicks continually make soft peeps, starting even a day or more before hatching. They are highly precocial, and leave the nest a few hours to one or two days after hatching. Heavy rain can sometimes delay departure from the nest, as may have happened with two Horned Guan chicks that stayed put for six days. When they leave they are already capable of grasping branches and perches, although at first they can have difficulty keeping their balance. They are skilful at climbing through the vegetation and can flutter for short distances at three or four days old.

Both sexes brood the chicks on the roost, except in the curassows and the Horned Guan, where this task is carried out only by the female. During the night the adult normally protects the small chicks by sheltering them under a half open wing, sometimes with one chick under each wing. A female Great Curassow has been recorded feigning injury in order to distract the attention of possible predators from her chicks.

In other Galliformes chicks feed themselves by picking up little bits of food that they find by wandering about, but cracid chicks are fed by their parents, or only by the mother in some species. The adult offers them food in the tip of the bill, either regurgitated, in chachalacas and guans, or not, in curassows (see Food and Feeding). Soon the chicks gradually begin to feed themselves, although when they are half-grown they still continue to receive food from their parents from time to time. One adult Rufous-vented Chachalaca was seen making palm fruits fall, apparently deliberately, for half-grown chicks that waited on the ground below to eat the fruit. Although they remain in loose flocks for a considerable time, young chachalacas and guans become comparatively independent of their parents more quickly than do curassows. Young Red-billed Curassows, for example, remain practically inseparable from their mother until they are more than four months old.

The age at which cracids reach sexual maturity is not definitely known. Data from captivity and the capture of birds not in breeding condition during the breeding season, suggest that breeding normally starts at two years of age, and this has been confirmed in some female Red-billed Curassows, although other conspecifics do not seem to begin until they are three. However, chachalacas, given their small size, are probably ready to breed at one year old. There may also be differences between the sexes, as experience in captivity suggests that male Horned Guans need four years to become sexually mature, whereas some females can breed after only one.

Virtually nothing is known of breeding success in this family. One exception is the Plain Chachalaca, in which successful nesting was recorded in 65% of 135 nests studied over four years in the Santa Ana National Wildlife Refuge, Texas; 4% were abandoned; and 30% destroyed, mainly by mammalian predators, such as raccoons (*Procyon lotor*) and opossums (*Didelphis marsupialis*), and also by snakes. Trinidad Piping-guans are also said to suffer some nest predation by snakes, while two Crested Caracaras (*Polyborus plancus*) were seen plundering a Chaco Chachalaca's nest in Bolivia. Other birds of prey, jays and monkeys also undoubtedly rob cracid's nests

The White-crested Guan is generally reckoned to be the most handsome member of *Penelope* due to its more contrasted, colourful plumage. This species has a fairly small range in Amazonia, where it appears to be restricted to areas of dense, pristine forest. For this reason, despite the lack of any evidence of a decline, the species is currently considered to be near-threatened. It has been bred sporadically in captivity in various zoos and is at present the subject of a captive breeding programme in the Cracid Breeding and Conservation Centre, in Belgium.

[*Penelope pileata*.

Lynx]

occasionally. The young are assumed to suffer high mortality, especially due to predation by both birds and mammals, and, like all gamebirds, cracids tend to be favourite prey species. Predators include: several species of jungle cat; larger mustelids, like the eira (*Eira barbara*); the Ornate Hawk-eagle (*Spizaetus ornatus*), known as "Curassow Hawk" in places; Harris's Hawk (*Parabuteo unicinctus*), which has been seen killing guans in different areas; the Collared Forest-falcon (*Micrastur semitorquatus*), which seems to capture West Mexican Chachalacas frequently; and the Black-chested Buzzard-eagle (*Geranoaetus melanoleucus*), which has twice been seen recently catching White-winged Guans, a threatened species. However, once cracids reach maturity, they are thought to be fairly long-lived, especially the curassows. In captivity, a female Great Curassow died at 24 years old, having laid eggs until she was 23, and there are several other records of birds over 20 years old, including Razor-billed and Wattled Curassows. Despite the effects of predation and low productivity, cracids maintain their numbers well where they are not persecuted by man.

Movements

All cracids are essentially non-migratory, although some local movements occur in many species. Perhaps the most regular movements are the vertical ones undertaken by several of the mountain species. The Andean, Wattled and Sickle-winged Guans, and maybe also the Northern Helmeted Curassow, seem to perform some seasonal altitudinal movements that may be related to the search for available fruit. Outside the breeding season, the three guans have all been recorded above or below their normal altitudinal ranges on various occasions, and similar movements have also been noted in lowland species that occupy more mountainous areas in parts of their ranges. Such are the cases of the Crested Guan in some areas of Colombia, of

the Dusky-legged Guan in north-west Argentina, and of the Black-fronted Piping-guan in Brazil. This last species, now extirpated from most of its original range (see Status and Conservation), used to migrate vertically in the Serra do Mar, São Paulo, in connection with the availability of palmito fruits that ripen earlier in the lower areas. In fact, similar movements still occur in the population that inhabits the Ilha do Cardoso State Park, where the species is present at altitudes of 100-900 m.

Other kinds of movement noted in some cracids are connected with wet seasons. The White-winged Guan concentrates in evergreen thickets at the height of the dry season, and at some of the localities where it persists, it is only present at certain times of year. In the Sierra de Macarena, Colombia, Salvin's Curassow retires during the dry season to valley bottoms or woody gullies where there is still water. The concentrations of Yellow-knobbed Curassows during the dry season at the remaining pools in the Venezuelan llanos are also well known.

Other, more typical migratory movements related with seasonal changes of temperature are also known. The Black-fronted Piping-guan's range, because of its latitude, is more affected by climatic seasonality than are those of most other cracids; indeed, at the turn of the century it was apparently migratory in south central Rio Grande do Sul, Brazil. It appeared in the area between May and June, and after breeding there left in December. It also appeared seasonally in Santa Catarina, in March and April, with the ripening of the fruits of the pindaúba (*Xylopia*), an important component in its diet. Normally birds arrived in small groups, but in years with abnormally cold winters there were veritable invasions of the species. They seem to have moved in groups of 4-16 birds. Thus, although the drastic decline of the species now masks the fact, this species is probably the cracid most prone to authentic migration. Its congeners may share a certain tendency to migrate, as both the Trinidad and the Blue-throated Piping-guans move over large areas in search of fruit, and

the latter even migrates locally up or down rivers in Mato Grosso, Brazil.

Relationship with Man

The cracids have always been well known to local human populations. Maya remains bear witness to this, with cracids featuring on various archaeological finds, and on pictograms and manuscripts. The peninsular Maya language has names for each of the cracid species present on the Yucatán Peninsula, and different names for the male and the female of the two species with marked sexual dimorphism, the Highland Guan and the Great Curassow. It is also believed that a cracid, probably the Crested Guan, was the "bird of dawn", a legendary bird of great importance in Mayan mythology, that was later substituted by the Spanish-introduced cockerel. In Mayan tradition, the "bird of dawn" was created apart from other animals to act as a sentinel, to announce when Kisin, the "Lord of Death and Darkness", struck Hachakyum, the chief Sun god. Each morning, at that moment of apparent indecision between light and darkness, the call of the "bird of dawn" would warn the son of Hachakyum, who would come to rescue his father and defeat Kisin. The great influence of Mayan culture probably explains why representations of cracids also appear in other areas of Central America.

The Mayan legend of the "bird of dawn" suggests one of the principal reasons why cracids do not go unnoticed by their human neighbours: their remarkable vocalizations (see Voice). This is particularly so in the case of the noisy chachalacas, as their songs are often "interpreted" by the local people, who put words to them, which, when repeated quickly, mimic the songs quite well. In Colombia, for example, the female Chestnut-winged Chachalaca is said to ask the male "¿Se cae la casa?", (Is the house falling down?), to which he replies "¡No se cae, no se cae!" (No it's not, no it's not!). In the Mato Grosso of Brazil, the song of the Chaco Chachalaca is interpreted as "Quero casar pelo natal" (I want to marry at Christmas).

Another obvious aspect of man's close relationship with cracids is the fact that these birds are nearly always among the favourite targets of local hunters. This has been so since ancient

times, as shown by Mayan use of their feathers for arrows and their flesh for food. Their Lacandón descendants and nearly all the local peoples in the cracids' range continue these uses to this day. The meat of various species has often been described as excellent, although this opinion is not unanimous, and the large, strong tail and wing feathers make excellent fletches for arrows. Chachalacas, which inhabit more open, settled areas, are particularly exposed to this persecution and are also popular amongst sport hunters because, although they do not offer good wing shooting, their hunting requires long waits and challenging tracking. Paradoxically, however, the chachalacas are the cracids which best withstand hunting pressure, and are almost the only members of the family for which hunting does not constitute a serious threat (see Status and Conservation).

Over the centuries, cracids have also been caught to be kept in captivity. In some areas it is particularly common for tame curassows, guans or occasionally chachalacas to be kept like poultry in villages. If they are kept with chickens, however, they will often attack or even kill them. The claim that a cross between a chachalaca and a chicken results in an excellent fighting bird has no basis, as no hybrids of Cracidae with any member of any other family have ever been reported scientifically. Given their large size and striking appearance, cracids are also highly regarded by aviculturists, though less so in the case of the less handsome chachalacas. There are records of cracids being exported to Europe in the seventeenth century. The curassows owe their name to the fact that the first of these birds to arrive in Europe were sent from the island of Curaçao, in what is now the Netherlands Antilles, whence they had no doubt been imported from other areas, as cracids do not live wild on this island.

After their arrival in Europe, it was thought that their domestic breeding might be profitable, given their great size and their more trusting nature than, for example, turkeys (*Meleagris*). Attempts to do so failed, however, due largely to their small clutch size, their vulnerability to low temperatures, which very quickly freeze their feet, and the fact that most species are apparently monogamous. Nonetheless, they are not particularly difficult to breed, especially in temperate or hot climates, and more than half of the species have now been bred successfully in zoos or private collections. The survival of some of the most

The Black Guan is another species which is considered to be near-threatened essentially because of its restricted range. It is found only in the mountains of Costa Rica and Panama, where a great deal of its habitat has been destroyed or has undergone major transformations; in addition, the species is intensively hunted for food in many areas. Fortunately, it is still locally common in some of the remoter parts of its range and in a few protected areas, most notably in the Monteverde Cloud Forest Reserve, where its density was recently estimated at four pairs per square kilometre.

threatened species indeed relies on various programmes of captive breeding (see Status and Conservation), although the capture of birds for trade has been decidedly detrimental for several species.

Status and Conservation

There are still some large gaps in what is known about the Cracidae, including basic aspects of their biology. It may seem rather surprising, therefore, that their status, at least at a general level, is fairly well known. This is in part due to the co-ordination and exchange of information between most field researchers working on cracid species under the auspices of the ICBP/IUCN International Cracidae Specialist Group. This co-operation allowed the chairman, S. D. Strahl, to prepare a detailed Action Plan in 1990, listing each species' status and conservation priorities, country by country. Another contributing factor was the publication in 1992 of the ICBP/IUCN Red Data Book for the Americas, under the direction of N. J. Collar. All information available about threatened Cracidae, a family endemic to the region, was thus comprehensively drawn together.

With all the information to hand, it is clear that the status of the chachalacas is quite different from that of the guans and curassows. Thus, none of the twelve species of *Ortalis* is currently considered globally threatened, and only the Rufous-headed Chachalaca (*Ortalis erythroptera*) is listed as near-threatened. Of the 24 species of guan, however, seven are classed as threatened, the Bearded, Cauca, White-winged, Chestnut-bellied and Horned Guans and the Trinidad and Black-fronted Piping-guans; another seven, the Baudo, Red-faced, White-crested, White-browed, Wattled, Black and Highland Guans, are considered to be near-threatened. The situation of the curassows is even worse: six of the 14 species are threatened, namely the Alagoas, Blue-billed, Wattled and Red-billed Curassows and the Northern and Southern Helmeted Curassows, and these include the most severely threatened members of the family.

The difference in status between the chachalacas and the other cracids can be explained by their differing habitat requirements (see Habitat). As guans and curassows are basically forest species, often dependent on primary forest, they are seriously affected by any alterations implying some degree of deforestation, a process which is taking place, to a greater or lesser extent, throughout the Neotropics. In fact, habitat destruction is causing declines, and even local extinctions, in nearly all species of guans and curassows, not just the threatened species. Differences in overall status are due, to a great extent, to the sizes of each species' range and whether this range includes sufficiently large areas of habitat that is protected, by the remoteness of the area, the inaccessible nature of the terrain, or, more rarely, efficient conservation measures.

The chachalacas, on the other hand, avoid dense forest and are even favoured by some of these changes, often appearing in areas where they did not occur until the primary forest was cleared or converted into plantations. When habitat destruction is very severe, however, it also leads to the disappearance of chachalacas, and this has led to marked local population declines in many species. This danger is, of course, greater in species with more restricted ranges, so it is not surprising that the Rufous-headed Chachalaca is the least secure of the chachalacas, as it is the most localized species, restricted to the now heavily transformed lowlands of western Ecuador.

Following habitat destruction, the second most important threat to cracid survival is hunting, be it for food or feathers, for trade or for sport. Several studies show that cracids constitute the largest avian biomass taken by the various kinds of hunters in Neotropical forests.

These two factors combined, habitat destruction and hunting, are nearly always sufficient to account for the delicate situations of the threatened species in the family. All three natural groups are subject to a greater or lesser degree of hunting, but their ability to withstand it is quite different. The wary chachalacas, accustomed to moving through open habitats, are able to survive even in areas where they are hunted intensively throughout the year. The guans and particularly the curassows, however, are very sensitive to hunting pressure and tend to disappear rapidly from the vicinity of settled areas. There are several reasons for their extreme vulnerability to hunting: their large size; the ease with which they can be located when making their courtship vocalizations, a period when persecution is particularly harmful; the trusting nature of many species when they are not used to persecution; and their low productivity, much lower than in the vast majority of Galliformes (see Breeding). A quantitative estimate of how curassow populations are affected by hunting was obtained by J. M. Thiollay in French Guiana. The estimated density of Black Curassows in areas where there was no hunting within 50 km or more was between 7.28 and 9.46 birds/100 ha; in zones with hunting 3-20 km away, it fell drastically to between 0.51 and 2.25; but it slumped to between 0.05 and 0.73 in regularly hunted areas.

Of all the threatened cracids, the Wattled Curassow is perhaps the least known in terms of status, and it is the only one classed as Indeterminate. Although it is not known ever to have been common, in the few areas of its range for which there are old estimates and where field work has recently been carried out, comparisons of the figures consistently show serious declines, or even that the species has disappeared completely from the area in question. In fact, despite the increase in ornithological exploration in recent times, there are more records of the species in old texts than in works written during the present century. On the other hand, some recent records show that the species inhabits some areas where it was hitherto unrecorded. The species has been hunted intensively in Peru and northern Bolivia, and almost certainly in many other areas. In addition, particularly in Brazil, the destruction of large areas of *várzea* forest, a habitat particularly favoured by the species, must also have played an important part in its decline. Nevertheless, there are still large areas within its range which are well conserved, so the causes of its apparent overall decline are still, therefore, not well understood.

The Bearded Guan of south Ecuador and north Peru has one of the smallest ranges of any cracid, in a region where forest destruction has been severe.

The species is classified as Vulnerable/Rare, and its future may be bound up with that of its main stronghold, the Podocarpus National Park, a protected area which is currently suffering from the presence of many casual gold prospectors.

[*Penelope barbata*.
Photo: Josep del Hoyo/
Lynx]

Despite a marked regression, the White-browed Guan manages to survive in areas of dense human population, thus indicating a certain capacity for adaptation, and it is presumably for this reason that it is only considered near-threatened. As so often, the combination of habitat destruction and hunting pressure is responsible for its decline.

[*Penelope jacucaca*,
Brazil.
Photo: Haroldo Palo/
NHPA]

Two species, the Cauca Guan and the Red-billed Curassow, both have very small populations in restricted ranges. Thus, although these populations are largely protected, both are classified as Rare, and are thought to require close monitoring.

The Cauca Guan is almost completely restricted to the middle and upper Cauca Valley, in western Colombia, where the humid forests inhabited by the species have been widely destroyed. This destruction, almost certainly in conjunction with hunting, led to such a steep decline that in the 1970's and the early 1980's the species was thought to be on the verge of extinction. Subsequently, however, at least three small, apparently stable populations have been found in protected areas. The first priority now for their conservation is the elimination of poaching that still goes on in two of these three protected areas, while further surveys may show that the species still survives elsewhere.

The Red-billed Curassow also has a limited range in a highly transformed area, in this case the lowland Atlantic forest of Brazil. Although it was apparently fairly widespread in the past, the intense forest destruction in this area, combined with direct persecution of the species particularly for trade, has devastated the population, now estimated to total a few hundred birds. They survive in six or seven forest patches, five of which are in protected areas; the bulk of the population inhabits two of these areas, the adjoining Sooretama and Companhia Vale do Rio Doce Reserves in Espírito Santo. However, the recent extinction of some populations in theoretically protected areas demonstrates the uncertain future of this species.

This same species is one of the cracids with the largest populations in captivity, where it has been bred successfully, and to date it is the only species being reintroduced experimentally. Of the 400-450 birds in captivity, over half are at the Fundação Crax, near Belo Horizonte in Minas Gerais; this was started from the private collection of the Brazilian aviculturist R. Azeredo, with the financial and technical aid of Stichting Crax in the Netherlands, and the Cracid Breeding and Conservation Centre in Belgium. The high breeding success of this stock has enabled the reintroduction of some birds to the wild. In December 1990, following a six-week quarantine period, 15 pairs, which had been raised together and were about 18 months old, were put in a huge aviary in an area of 1460 ha of regener-

ating rain forest owned by the company CENIBRA near Ipatinga, Minas Gerais. They were kept here for ten months, while their diet was gradually changed until it consisted basically of leaves, shoots and fruits of plants growing in the release area. After their release their adaptation to their new surroundings was carefully monitored: within a year four birds had been killed by predators; one had died due to unknown causes; and two had been captured by poachers, even though the reserve was closely watched by guards, and despite educational programmes carried out in neighbouring areas. Nevertheless, over 20 birds survived in the reserve, apparently well adapted, and several males were seen performing breeding displays. In July 1993, another 37 birds were introduced into the aviary in preparation for a second release at the end of the year. This time the birds were to be marked with colour rings to allow individual recognition and some were radio-tagged so that they could be tracked. The project has received some criticism, because it is not known whether the species previously inhabited the area and because of habitat deficiencies, but there is much value in examining the difficulties and potential of reintroduction from captive stock. This is particularly true given that the survival of several cracids could depend on the success of this type of programme.

The populations of another five declining cracids are only partly protected, and these species are considered Vulnerable. They are the Bearded, Chestnut-bellied and Horned Guans, the Black-fronted Piping-guan and the Southern Helmeted Curassow.

The Bearded Guan, with a fairly limited range in the humid montane forests of southern Ecuador and adjacent north-western Peru, was considered to be common at the turn of the century, but has now been reduced to a few populations which are thought not to exceed a few thousand birds in total. The sharp decline is due to the destruction of large areas of its habitat, and the species' particular vulnerability to hunting due to its confiding nature. Only one of the currently known populations is protected, in the Podocarpus National Park in southern Ecuador. The situation would have worsened drastically, but the concessions for open-pit mining covering 99% of the park, were withdrawn in 1993, following a determined campaign by various conservation bodies, including BirdLife International (ICBP). Unfortunately, the opening up of trails in

previous years had already made access to the park easier for poachers and casual gold prospectors. It has been estimated that in 1993 some 200-500 of these miners were digging illegally in the park and had deforested some areas. Increased conservation efficiency in this park and the creation of other reserves in various parts of Ecuador and Peru are essential for the survival of this and other species of the region, one of the areas of highest endemism in all South America.

Very little is known about the Chestnut-bellied Guan; indeed, there have been remarkably few records. It is scattered over a wide area of central Brazil, but its specific habitat requirements are not known. Nor have the exact causes of its apparently low population been identified, although it is very possible that, like most species in this family, it suffers hunting pressure; it has probably also been negatively affected by the agricultural developments within its range. On the other hand, it may be a species which is naturally very localized or very secretive. In any case, there is the alarming fact that it has only been reported from one protected area, the Araguaia National Park, in Tocantins, where it is believed to live in small numbers. Surveys to delimit its current distribution and status are the first priority for its conservation.

In terms of status, the Horned Guan is one of the species about which most has been written. Despite a very limited range, in southernmost Mexico and adjacent western Guatemala, various reports show that it was fairly common at the end of the nineteenth century. It has undergone a steady decline in the twentieth century due to the destruction of its humid montane forest habitat, mainly for farming and coffee plantations; and also due to hunting, as these large, confiding birds are especially vulnerable, and pressure intensified as the number of coffee plantations increased, the birds being a tempting source of food for the workers. By the end of the 1970's it was estimated that the total population was below one thousand birds. The recovery of this highly distinctive bird was one of the ideas behind the creation of El Triunfo Biosphere Reserve, in Sierra Madre de Chiapas, which managed to stop the destruction of forest that had been being carried out by settlers throughout the 1960's. This was accompanied by the setting up of a global conservation programme, supported by the Brehm Fund and Wildlife Conservation International. In 1987, the Mexican ornithologist F. Gonzalez-Garcia began a long-term study into the species' biology and ecology which has now made it one of the best known of all the Cracidae. Since 1988, local educational campaigns have been carried out in the villages near the reserve. A captive breeding programme is also under way in the private collection of J. Estudillo, near Mexico City. After several years in which only infertile eggs were laid, the study of the species' dietary needs, of bird management techniques, and of artificial incubation of eggs has resulted in

considerable success, 15 birds being raised to maturity between 1989 and 1992. If the habitat is conserved, some of the areas where the species has been eradicated by hunting may be repopulated in the future. The symbolic significance of the Horned Guan has encouraged the setting up of a few protected areas in Guatemala too, although large proportions of the surviving populations in both countries are found in areas with no form of protection; preserving these areas is the maximum conservation priority for this species.

Another species that has aroused much interest is the Black-fronted Piping-guan. It is another victim of the devastating destruction that has taken place in the Atlantic forest of eastern Brazil and adjacent eastern Paraguay and north-eastern Argentina, combined with extremely intense hunting pressure. These two factors have resulted in a marked reduction of the species' range, from the northern half of which it has practically been eliminated; they have also led to a drastic decline in overall numbers. In the scattered sites where it still survives it is now rare or very rare, but there is evidence that it was formerly abundant, at least in some areas: the record of about 50,000 birds killed in an area of Santa Caterina during a few weeks in the cold winter of 1866; and photos of "pyramids" of birds taken by hunters in Paraná in the 1930's. It is very likely that this species' migratory habits and its partiality for the fruit of the palmito (see Movements, Food and Feeding), a palm often exploited by man, hinder its conservation in the generally small pockets of forest that remain in this region. Small populations of the species still survive in various protected areas, but its recent extinction in Sooretama Reserve, Espírito Santo, apparently due exclusively to poaching, shows the limited safety this implies. There are also populations in areas without any form of protection in all three countries of its range. The creation of reserves in these areas and the improvement of conservation measures in those already existing must be the main priorities to ensure the survival of the species. With these aims achieved, already successful captive breeding programmes might allow some reintroductions or the reinforcement of some populations with low numbers. Again, the reserve of Sooretama serves as a warning of potential difficulties, as an attempt to reintroduce the species there in the 1970's failed.

The Southern Helmeted Curassow is a species about which hardly any information had been gathered until very recently. It was not discovered until 1937, in the Yungas de Cochabamba, central Bolivia, and only four specimens were known of until the 1960's. In 1969, however, another two birds were collected in the Cerros del Sira, eastern Peru, over 1000 km to the north of the area in which the species was hitherto known, and they were described as a new subspecies. Although they are known to be hunted by both natives and professional hunters, the

This is one of the first chicks hatched in a captive breeding programme of the White-winged Guan that is being carried out in north Peru, very close to the natural range of the species. Classified as Endangered and judged to be in a critical situation, this species may have a maximum population of only a few hundred birds.

[*Penelope albipennis*.
Photo: Gustavo del Solar]

There is ample evidence to suggest that the Black-fronted Piping-guan was once a most abundant species. It is now seriously threatened, principally due to the extensive destruction of the Atlantic forests of Brazil, to which the bird is endemic. It is currently kept in captivity in several zoos and institutions, where it is bred without too much difficulty.

[*Pipile jacutinga*.
Photo: Josep del Hoyo/
Lynx]

The Northern Helmeted Curassow, another endangered cracid, suffers pressure from indiscriminate hunting, both for food and for its "helmet", which is used by the local Indians for making necklaces. These "trophies" were displayed on the wall of a bamboo hut in western Venezuela.

[*Pauxi pauxi pauxi*,

Geerlings]

The status of the Southern Helmeted Curassow is amongst the least known of all cracids. Nevertheless, the paucity of records of the species since its discovery explains why it is classified as Vulnerable/Rare. The species is kept in captivity only in the aviaries of J. Estudillo, near Mexico City, where it has been bred successfully.

[*Pauxi unicornis unicornis*.

Lynx]

reason for their rarity is unclear, and this may well be a naturally rare and localized species. Another factor to consider is the very limited amount of ornithological field work carried out in this region, which has no doubt contributed to the fact that such a remarkable species has gone almost unnoticed. This situation started to change in 1987 when Cox and Clarke began their study (see Breeding) on the species' status and requirements in the Amboró National Park, Bolivia, the only protected area in which the species is known to occur. It was found that a reasonably large population lived and bred in this park of 180,000 ha, and anti-poaching measures were stepped up, probably leading to the slight increase in numbers detected very recently. In addition, much new information about the species was collected, for instance about its vocalizations, local movements and breeding behaviour, including the discovery of the first nest. This information may also be useful for the protection of the species in other parts of its range. In the mid-1980's some birds were captured live and taken to the collection of J. Estudillo in Mexico, where they are now breeding successfully. Recently, in 1992, a bird was seen in the Cerros de Távara, southern Peru, about half way between the two known populations, although it is not known which race was involved. This underlines how little is known regarding the species' range and offers reasonable hope of the existence of further populations as yet undiscovered. Expeditions are urgently needed to search for unknown populations, particularly in the foothills of the Andes and outlying ridges in the frontier area between Peru and Bolivia; also, reserves should be declared in all areas known to hold populations.

Five species of cracids are currently classified as Endangered, although in the ICBP/IUCN Red Data Book further distinctions are drawn: the cases of the Trinidad Piping-guan and the Northern Helmeted Curassow are considered "serious", whilst those of the White-winged Guan, and the Alagoas and Blue-billed Curassows are "critical". This last species is noteworthy because no wild populations are known; the urgent action required for all Endangered species, in order to avoid rapid extinction, can, in this case, only be put into action once a population is found.

The Trinidad Piping-guan has one of the smallest populations of any cracid, estimated in 1980 at about 100 birds, in

two well separated populations, in the Northern and Southern Ranges of the island of Trinidad. Once again, the combination of habitat destruction and illegal hunting has been responsible for the dramatic decline of the species, which was widespread and abundant in the second half of the nineteenth century and still maintained large numbers during the 1940's. Despite this slump, no conservation measures were taken until very recently, due partly to the fact that this form has traditionally been considered a race of the closely related Blue-throated Piping-guan. Its recent recognition as a separate species, although not accepted unanimously (see Systematics), has made it Trinidad's only endemic bird species and appears to have stimulated interest in its conservation. In the 1980's the government organized various environmental education campaigns, including a television advert, which have raised the popularity of the bird on the island. However, urgent measures are still required: the species has been legally protected since 1963, and the laws

must be put into practice, as must those against squatting and logging which still continue in the areas it inhabits, although nearly all of them are in forest reserves or state forests. A system of national parks including the key areas for the species has been on the agenda for some time, but has still to be put into action.

The situation of the Northern Helmeted Curassow is similar to that of other threatened cracids. Deforestation and persecution, not only for food but also for the helmet which is used by Indians to make necklaces, have made it rare to very rare in most of the areas for which there are data, mainly the mountains of north Venezuela. This indicates a sharp decline, as in parts of this region the species was reported to be common in the nineteenth century and still fairly common in the 1950's, although it probably lives naturally at fairly low densities. Although reliable information is not available, it is feared that the species is also under pressure in the Andes, both in Venezuela and Colombia, and in the Sierra de Perijá, where a separate subspecies occurs.

The Blue-billed Curassow is without doubt one of the most critically threatened cracids. The last sighting of a bird in the wild was in 1978, at Puerto Berrío in Antioquia, Colombia. However, the recent illegal importation into Japan of four birds apparently captured in the wild in Colombia raises hopes that a small population survives, although if this so, it is still clearly being exploited for trade. The reasons for the critical status of this species, compared to that of congeners with similar ecological needs, are centred on its restricted range in the lowlands and foothills of north Colombia, and the fact that this is an area where deforestation has been particularly severe, and hunting pressure equally heavy. This is the only Endangered cracid for which no conservation measures have yet been taken; some birds have been bred in a few collections, but as yet there is no captive breeding programme on which a recovery plan might be based. Even more urgently needed is a survey of any sizeable remnants of forest in its range, with a view to establishing its current status and setting up suitable reserves.

One of the most remarkable cases is that of the White-winged Guan. The species was described in 1877 by L. Taczanowski from a male collected in the previous year on a mangrove covered island in the delta of the River Tumbes, in

north-western Peru. The species was already thought to be on the point of extinction due to continual persecution, although the locals explained that it had been common only 30 years before. In the same year, 1877, a female was shot and a chick taken and hand-reared. These two birds, together with the type specimen, were the only museum skins in existence for many years. Nothing further was known of the species, despite specific searches by M. and H. W. Koepcke in the 1950's. This complete lack of information led to the questioning of its taxonomic validity (see Systematics).

In 1977, after the species had been thought extinct for a century, G. del Solar and J. P. O'Neill visited the Andean foothills in Lambayeque Department, going to a small agricultural plot owned by a local farmer who had assured them that guans with white wings lived in the area. Accompanied by the farmer, at an altitude of about 600 m, they sighted the first White-winged Guan to be seen by biologists in 100 years. By the end of the day they had recorded six to eight birds. The rediscovery had taken place in dry forest, quite a distance from the coast, despite the fact that all the old records were from coastal areas with mangroves. A year later, E. Ortiz began a detailed study of the feeding and habitat requirements of the species, its population and its chances for continued survival, with the result that the species became better known than many other guans with much larger populations and more extensive ranges. It is currently estimated to have a population of a few hundred birds, which, lamentably, still suffer from habitat loss and hunting pressure. An environmental education campaign is urgently required so that the local population can develop an interest in the conservation of this species, which is not found anywhere else in the world. The survival of the species also depends on the efficient implementation of the legal measures passed in 1980 to protect the habitat and ban hunting, which have so far proved purely nominal. On the positive side, a captive breeding programme has been started in the area, with remarkable success, no less than four pairs breeding.

Despite the precarious status of many of the species already discussed, no cracid is in a more desperate situation than the Alagoas Curassow. A detailed description of this bird, including an unmistakable illustration, appeared as far back as 1648 in the German naturalist G. Marcgraf's *Historia Naturalis Brasili-*

At present, the Red-billed Curassow is the only cracid that is the object of a documented reintroduction programme; this is being carried out in a reserve near Ipatinga, in Minas Gerais. This species, endemic to the heavily ravaged Atlantic forests of Brazil, is certainly in an alarming state in the wild, with only a few hundred individuals remaining, scattered among six or seven forest patches. The reintroduction programme is based on a large captive population kept at the Fundação Crax, in Minas Gerais, where several dozen pairs breed each year.

[*Crax blumenbachii*.
Photo: Luiz Claudio
Marigo/Bruce Coleman]

This historic photograph shows some of the founder members of the only existing captive population of the Alagoas Curassow, which resides in the collection of P. M. Nardelli, near Rio de Janeiro. This is the only cracid species considered to be extinct in the wild, so its future depends entirely on this population, which in 1993 consisted of 34 birds, most of which were hatched in captivity. The photograph clearly illustrates the main characteristics which distinguish this species from the Razor-billed Curassow (*Mitu tuberosa*), with which it was traditionally considered to be conspecific: these are the bare patch of skin around the ears; the two-tone colouring of the bill; and the pale brown, rather than pure white, tail tips.

[*Mitu mitu*.

Photo: Pedro Nardelli]

liae, a work that would be used by Linnaeus as the foundation for the description of those Brazilian species included in his *Systema Naturae*. However, the total lack of data ever since, and the lack of even a single specimen (see Systematics), led to ever-increasing doubt about the existence of this species; it was even thought that Marcgraf's description might have been based on a Razor-billed Curassow imported from the Amazon.

In 1951, however, on a tour of Alagoas, the Brazilian ornithologist O. Pinto found the corpse of a curassow that had been killed in the area. Comparisons with skins of Razor-billed Curassows showed various differences, demonstrating that the old description by Marcgraf was precise and correct. The species was assumed to be very rare, due to the extreme destruction of the habitat and the intense hunting pressure, and by 1970 some workers considered it to be definitely extinct, while others estimated its total population at less than 20 birds. In 1978 and 1979, in remnants of forest that were being converted into sugar cane plantations for a distillery, five birds were captured by the Brazilian aviculturist P. M. Nardelli. These were the founders of the captive population kept in the Zôo-Botânica Mário Nardelli, near Rio de Janeiro, the subject of various studies (see Systematics). The birds have bred fairly well, both naturally and with artificial insemination, 37 young having been reared. In 1993 the population stood at 34 birds.

As regards the wild population, the last reference corresponds to a bird seen in 1987, and killed shortly afterwards, so it is now believed extinct in the wild, or, at most, that a few individuals survive with no viable future. Appropriate management of the captive stock, perhaps the entire world population of the species, is, therefore, of fundamental importance and would seem to call for the involvement of the appropriate Brazilian government institutions and international conservation bodies. In any event, the short-term possibilities of implementing a programme of reintroduction are remote, as in 1992 it

was calculated that only 800 ha of lowland forest remained in Alagoas, with an estimated capacity of some 32 pairs; even at this stage the area is still totally unprotected.

All these cases indicate that both research and conservation measures must urgently be stepped up for the cracids, not just for the ethical or aesthetic benefits of conserving these interesting birds, but also for much more pragmatic reasons. Cracids are important both as a source of protein for local human populations and as seed dispersers of numerous plant species (see Food and Feeding), a vital function for the long-term maintenance of healthy forests. In addition, their very sensitivity to the two major forms of human intervention, habitat loss and hunting, and the fact that they are normally fairly easy birds to survey means that, together with the primates, they are amongst the most useful groups to use as indicators of habitat quality in Neotropical forests, and of the efficiency of various types of management programmes. Only the realization by governments that cracids are a valuable national resource, with important biological and ecological roles, can reverse the currently alarming trends of many of these species.

Subfamily PENELOPINAE

Genus *ORTALIS* Merrem, 1786

1. Plain Chachalaca

Ortalis vetula

French: Ortalide chacamel **German:** Blauflügelguan **Spanish:** Chachalaca Norteña
Other common names: Common/Mexican/Eastern Chachalaca; Northern Chachalaca (*mccallii*); Utila Chachalaca (*deschauensei*)

Taxonomy. *Penelope vetula* Wagler, 1830, Mexico.

O. poliocephala and *O. leucogastra* formerly considered races of present species. Population of dry interior valley of Chiapas, S Mexico, was separated in race *vallicola*, but differences slight and not usually recognized. Isolated population in Costa Rica may represent undescribed race; sometimes assigned to *O. leucogastra*. In Chiapas, range meets, and may slightly overlap with those of *O. poliocephala* and *O. leucogastra* but hybridization not recorded. Four subspecies currently recognized.

Subspecies and Distribution.

O. v. mccallii Baird, 1858 - extreme S Texas (USA) and NE Mexico S to N Veracruz.
O. v. vetula (Wagler, 1830) - E & S Mexico, Belize, E Guatemala, Honduras, W Nicaragua and NW Costa Rica.
O. v. pallidiventris Ridgway, 1887 - N Yucatán.
O. v. deschauensei Bond, 1936 - Utila I, off N Honduras.

Descriptive notes. 48-58 cm; male 468-794 g, female 439-709 g. Plain coloration. Juvenile more olivaceous above. Races vary in size and coloration; nominate darker and more richly coloured than all other races; very dark variants of nominate race occasionally occur in S Mexico and Central America.

Habitat. Areas of tall brush vegetation, thickets, scrub and second growth in lowlands. In S Veracruz ventures along streamside tangles into rain forest, but in areas where meets or approaches range of *O. poliocephala* and *O. cinereiceps*, present species found in drier habitats. In Guatemala and Honduras, also occurs in lowland and pre-montane forest, from sea-level locally up to c. 1850 m. Race *deschauensei* found in mangroves covering three quarters of Utila I; also, formerly, in adjacent scrub patches.

Food and Feeding. Fruits of many kinds, including hackberries (*Celtis laevigata*, *C. pallida*), mesquite (*Prosopis glandulosa*), mangoes, palmettos, persimmons, wild grapes, figs, *Bumelia*, *Achros*, *Juniperus flacida*; fleshy fruit apparently makes up roughly half of diet. Also fresh green leaves, shoots, buds and twigs of several trees. Occasionally takes some insects from ground. Forages in groups of up to 15 birds.

Breeding. Mar-May in Yucatán and S Chiapas, Apr-May in Texas, Jul in Tamaulipas and Nuevo Leon. Nest is small, flimsy structure of plucked sticks, grasses and leaves, lined with a few green leaves, placed in dense vegetation (trees or bushes), usually at 1.5-7 (0.9-10) m above ground; of 209 nests examined in Texas, 204 (98%) were in trees and 5 (2%) in vines supported by trees; occasionally, no nest structure is used at all, with eggs laid on stubs, bare crotches or horizontal portions of limbs. Lays 3 eggs (2-4); incubation 22-27 days, most often 25; chicks are cinnamon buff, russet and black above, white below, with cinnamon buff band across breast. Apparently, some birds breed at 1 year old, others at 2. In Texas, overall success from 455 incubated eggs was 50%, with average of 2.5 chicks per successful nest.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Still common in much of range, and locally very common. Favoured by shifting agriculture practices, permitting fields to lie unplanted and become covered with thickets and light woods. In contrast, unable to tolerate intensive land use and mechanization of agriculture; in lower Rio Grande Valley, Texas, clearing for agriculture has eliminated species, except in a few protected areas; species is currently object of transplantation programme in several parts of S Texas; greatest density in USA in Santa Ana National Wildlife Refuge, with an average of 2-77 birds seen per hour of census effort. On Caribbean slope of Guatemala, is last cracid to disappear in face of human pressure. In Costa Rica, common in higher mountains of Nicoya Peninsula; scarce and local in NW Pacific lowlands. Heavily hunted throughout most of range. Race *deschauensei* local but not rare in 1936, but has declined severely since, due to intense hunting pressure; in 1962 total population of this race estimated at 50-70 birds; recently reckoned possibly extinct. Introduction of birds of race *mccallii* to Sapelo I, off Georgia, USA, in 1923 was initially successful, but population declined during 1960's, and no birds recorded since 1966. Quite common in captivity, where frequently bred. CITES III in Guatemala and Honduras.

Bibliography. Aldrich & Duvall (1955), Alvarez del Toro (1981b), Balda (1989), Bent (1932), Bond (1936), Brodkorb (1942), Christensen (1978), Davis (1965), Fleetwood & Bolen (1965), Griscom (1932), Johnsgard (1975), King (1978/79), Land (1970), Leopold (1959), Lever (1987), Lowery & Dalquest (1951), Marion (1974, 1976, 1977), Marion & Fleetwood (1978), Mayr & Short (1970), Miller & Griscom (1921a, 1921b), Mondragón & Baez (1981), Monroe (1968, 1970), Moore & Medina (1957), Ridgely & Gwynne (1989), Ridgway & Friedmann (1946), Root (1988), Rutgers & Norris (1970), Saunders (1950), Slud (1964), Smith (1966), Stiles & Skutch (1989), Taibel (1955), Terres (1980), Vannini & Rocksroh (1988), Vaurie (1965a), Wetmore (1943), Zepeda (1981).

2. Grey-headed Chachalaca

Ortalis cinereiceps

French: Ortalide à tête grise **German:** Graukopfguan **Spanish:** Chachalaca Cabecigrís

Taxonomy. *Ortalis cinereiceps* G. R. Gray, 1867, "north-west coast of America," error = Pearl Islands (?).

Forms superspecies with *O. garrula*, of which has been considered a race, but differs in voice and plumage, and, despite claims of sporadic hybridization in wild, they are separated by stretch of dense forest probably unsuitable for any *Ortalis* (see page 312). Several races (*frantzii*, *mira*, *olivacea*, *chocoensis*) proposed on basis of colour tone; but differences slight and essentially clinal. Monotypic.

Distribution. E Honduras, E & C Nicaragua, Costa Rica (except drier NW), Panama (including Isla del Rey in Pearl Is, where perhaps introduced by Indians) and adjacent NW Colombia.

Descriptive notes. 46-58 cm; 490-540 g, but one bird 682 g. Bright chestnut primaries conspicuous in flight. Juvenile browner, especially on head.

Habitat. Tangled thickets, light second growth woods, plantations, bushy abandoned fields, clearings and thinned out forests, in humid areas; lowlands or hills, locally up to 1700 m. Especially favours thickets where scattered, rapidly growing trees rise well above shrubs and vines. Shuns dense forest, although can occur in open borders of streams or sometimes in forest canopy, taking fruit from tree tops.

Food and Feeding. Fruits, e.g. spikes of guamo trees (*Cecropia*), berries (*Hamelia patens*, *Miconia hyperprasinia*, *Mantlingia calabura*, *Phytolacca*), drupes of acituno (*Simaruba glauca*) and guavas (*Psidium guajava*); guava fruits taken from branches of trees, not from ground. Also leaves, whole or pieces pecked off plant, e.g. of composite shrubs (*Veronia patens*, *Oyedaea verbesinoides*); occasionally insects. Has been recorded picking up food in rivers, and from branches over water or exposed rocks; during dry season, also visits rivers to drink, in morning and evening. Forages in groups of 6-12 or even more birds, at all vegetation strata; mainly arboreal, but does come to ground, where sometimes scratches to uncover food.

Breeding. Season variable, with laying recorded Jan-May, comprising at least part of rainy season. Nest is broad, shallow platform of sticks, leaves, grass stems, pieces of vine and inflorescences, placed in vine-draped bushes, tangles of creepers or small trees, at 0.9-2.4 m above ground. Usually 3 eggs (clutches of 2 may be incomplete); incubation over 22 days; chicks dull chocolate brown and sooty brown above, with some cinnamon marks, cinnamon and white below.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. In Costa Rica often common where not severely hunted. Fairly common in many areas of Panama, although has declined locally, e.g. on Isla del Rey (Pearl Is), and parts of Darién, where much hunted by Indians; well protected in Barro Colorado I Biological Reserve and quite numerous in wooded areas of Canal zone. Common in Colombia in 1986. Hunted for food throughout most of range. Adapts well to moderate habitat alterations, although has been extirpated from some areas by combination of deforestation and heavy hunting pressure. Birds from Panama introduced to Hawaiian Is in 1928, but died out. Uncommon in collections, but has bred. **Bibliography.** Haffer (1967), Hernández & Rodríguez (1988), Hilly & Brown (1986), Ridgely & Gwynne (1989), Ridgway & Friedmann (1946), Slud (1964), Skutch (1963, 1983a), Stiles & Skutch (1989), Vaurie (1965c), Wetmore (1965), Willis (1980).

3. Chestnut-winged Chachalaca

Ortalis garrula

French: Ortalide babillarde **German:** Rotflügelguan **Spanish:** Chachalaca Alirroja

Taxonomy. *Phasianus garrulus* Humboldt, 1805, Magdalena River, Colombia.

Forms superspecies with *O. cinereiceps*, which has been considered race of present species; they differ in voice and plumage, and, despite statements about sporadic hybridization in wild, they are separated by an area of dense forest probably unsuitable to any *Ortalis* (see page 312). Probably meets *O. ruficauda* in E of range (Guajira), but no evidence of hybridization. Monotypic.

Distribution. NW Colombia.

Descriptive notes. c. 53 cm; 630-755 g. Bright chestnut primaries conspicuous in flight.

Habitat. Dense tropical thickets, scrubby deciduous forest, tall second growth, and scrub, riparian woodland and mangroves of N coastal region. Lowlands up to c. 800 m. Avoids densely forested areas, but occurs in humid forest borders at N base of Andes.

Food and Feeding. Forages in groups of up to 12 birds.

Breeding. Apr. One nest built by male in captivity. Usually 3 eggs; incubation c. 26 days; chicks are brown and reddish brown above, buff and whitish below.

Movements. No information available; presumably sedentary.

Status and Conservation. Not globally threatened. Considered common in 1986, and probably remains so at present in much of range. Uncommon in collections, but has been bred.

Bibliography. Haffer (1967, 1975), Hernández & Rodríguez (1988), Hilly & Brown (1986), Mannkelle (1970), Mayr & Short (1970), Monroe (1968), Ridgway & Friedmann (1946), Taibel (1953), Vaurie (1965c).

4. Rufous-vented Chachalaca

Ortalis ruficauda

French: Ortalide à ventre roux **German:** Rotschwanzguan **Spanish:** Chachalaca Culirroja
Other common names: Rufous-tailed/Red-tailed Chachalaca; Rufous-tipped Chachalaca (*ruficauda*)

Taxonomy. *Ortalis ruficauda* Jardine, 1847, Tobago.

Race *ruficrista* has been considered separate species, but intergradation with *ruficauda* occurs N of Cúcuta, in N Colombia, and in hinterland of L Maracaibo, Venezuela; birds of latter area have been awarded different race, *balios* (see page 312). Population of Serranía de Macuira in Guajira Peninsula, NE Colombia, has also been separated in different race, *lampophonis*; validity doubtful, but deserves further study. Probably meets *O. garrula* in W of range (Guajira), but no evidence of hybridization. Two subspecies recognized.

Subspecies and Distribution.

O. r. ruficrista P. L. Selater & Salvin, 1870 - N Colombia and NW Venezuela.
O. r. ruficauda Jardine, 1847 - NE Colombia, N & NE Venezuela (including Margarita I) and Tobago; also Bequia I and Union I, Lesser Antilles, where probably introduced from Tobago.

Descriptive notes. 53-61 cm; 430-800 g. Greyish buff belly becomes rufous on undertail-coverts. Immature resembles adult. Races differ in size, tone of general coloration and colour of tail tip.

Habitat. Thorny deciduous brushland and forest in fairly open areas, e.g. *llanos* of Venezuela and Colombia; often near water, in gallery forest, along rivers or near lagoons. Marked preference for abandoned farmland, with mixed second growth and palms. Also clearings, in areas of humid forest. Mainly in lowlands; locally up to 1600 m in Venezuela. **Food and Feeding.** Fruits, tender shoots and leaves. Main food types are fruits, and occasionally leaves, of tree *Genipa caruto*, and nut-like fruits of palm *Copernicia tectorum*. Also leaves and flowers of guarumo (*Cecropia*). Forages in flocks of 4-20 birds, occasionally

over 50; usually in trees, sometimes on ground.

Breeding. Eggs in Jul in Colombia; all year round in Tobago, with peak Mar-Jun. Nests, made of twigs and leaves, have been found built in trees, usually 1-3 m above ground, occasionally as high as 20 m; only *Ortalis* definitely known to nest on ground sometimes, at edge of grassy glades. Lays 3-4 eggs, occasionally 2; incubation c. 28 days. One juvenile weighing only 300 g seen to fly as well as an adult.

Movements. No information available; presumably sedentary.

Status and Conservation. Not globally threatened. Common in Colombia. Secure in Tobago, where scrub habitat ideal for species; an increase in numbers was observed when many farms abandoned after a hurricane in 1963. Uncommon in collections, but has been bred.

Bibliography. Bond (1979), French (1973, 1992), Friedmann & Smith (1950, 1955), Herklots (1961), Hernández & Rodríguez (1988), Hilly & Brown (1986), James & Hislop (1988), Lapham (1970), Lever (1987), Mayr & Short (1970), Meyer de Schauensee & Phelps (1978), Ocampo (1981), Porras & Arriaga (1981), Ridgway & Friedmann (1946), Schmutz (1991), Snow (1985), Strahl & Silva (1988), Vaurie (1965c).

5. Rufous-headed Chachalaca

Ortalis erythroptera

French: Ortalide à tête rousse German: Rotkopfguan Spanish: Chachalaca Cabecirrufo
Other common names: Ecuadorian Chachalaca

Taxonomy. *Ortalis erythroptera* P. L. Sclater and Salvin, 1870, Babahoyo and Guayaquil, western Ecuador. Monotypic.

Distribution. W Ecuador and extreme NW Peru; may occur in SW Colombia (Nariño).

Descriptive notes. 56-66 cm; 620-645 g. Similar to *O. garrula*, but tail tips rufous and lower breast and abdomen more creamy.

Habitat. Dry deciduous forest, humid cloud forest, thickets, savanna and brushy areas, occasionally on agricultural land, in tropical coastal zone, inland to Andean foothills. In Sozoranga Mts, Loja (S Ecuador), occurs in dry *Ceiba* dominated deciduous forest, but is commoner in semi-evergreen and evergreen forest patches. Previously observed up to 1390 m, but recently seen at 1850 m, and heard apparently not much below 2500 m. Not found in arid regions.

Food and Feeding. Birds have been observed pecking leaves of cloud forest trees, and one bird had leaves in its stomach. A flock frequented a banana plantation; one bird seen on ground in a maize field. Forages mainly in small groups of 2-7 birds.

Breeding. In Peru silent, and probably not breeding, during dry season (Jun-Jul). Lays 3 eggs (in captivity); incubation 26-28 days (in captivity); chicks unevenly rust brown, chestnut brown to dark brown and black above, paler below.

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. Currently considered near-threatened. Has suffered range contraction which appears to be closely linked with habitat destruction, through logging, overgrazing and agricultural intensification. Uncommon to rare in all localities where known to occur in Peru, including some where forest is in good condition. More widely distributed in W Ecuador, but major decline also reported here; only 3% of Ecuador's lowland forest estimated to remain in 1991, when surviving patches were being further exploited and degraded. Previously unknown population found in 1989 in Sozoranga Mts, Loja; birds found in small patches (up to 30 ha) of remaining pre-montane forest, which has mostly been severely altered, and substituted by tall second growth and dense scrub; species also found on lower slopes, where much more extensive forest legally protected below 1000 m. In 1991 an international expedition (Ecuadorian Dry Forest Project) located c. 30 groups, totalling c. 100 birds at 7 localities in Loja and El Oro; maximum density of 6 calling groups in area of 1-2 km² recorded in Sozoranga area, where species fairly common in many forest remnants; some birds seen in degraded areas and on agricultural land, but habitat requirements poorly understood. Also suffers hunting pressure, though less than other, larger cracids; in Sozoranga, birds seen in forests adjacent to roads and near villages; relative unpalatability of adults may limit hunting to shortly after breeding season when tender juveniles present. Thought to be hunted by soldiers posted along border between Ecuador and Peru. Another probable threat is genetic isolation of groups in forest remnants. Occurs in several protected areas, including Machabilla National Park in Ecuador and Tumbes National Forest in Peru, although both subject to disturbance. Project under way in Ecuador to assess status and adaptability to secondary forest; efforts are being made to persuade government of Ecuador to buy a small, but important, patch of remaining forest in Sozoranga, which holds this and 6 threatened species of birds. Rare in captivity, but successfully bred in 1989 in Ornithological Zoo at Schmiding, Austria.

Bibliography. Arltmann (1990), Best (1992, 1993), Best & Clarke (1991), Best *et al.* (1993), Clarke (1990), Collar & Andrew (1988), Ortiz, E. & O'Neill (1988), Ortiz, E. (1981), Parker *et al.* (1982), Wiedenfeld *et al.* (1985).

6. Rufous-bellied Chachalaca

Ortalis wagleri

French: Ortalide à ventre marron German: Rotbrustguan Spanish: Chachalaca Ventricastada
Other common names: Wagler's Chachalaca

Taxonomy. *Ortalis wagleri* G. R. Gray, 1867, California and Mexico.

Forms superspecies with *O. poliocephala*, of which formerly considered a race; a few cases of hybridization in NW Jalisco were interpreted as proof of a narrow zone of intergradation in W Jalisco and W Colima, where intermediates were even considered a different race, *lajuelae*; cases of hy-

bridization may have resulted from escapes of imported *O. poliocephala* (see page 312). Population of Sonora was considered a different race, *griseiceps*, but not usually recognized. Monotypic.

Distribution. W Mexico, from S Sonora S to NW Jalisco.

Descriptive notes. 62-67 cm. Most richly coloured *Ortalis*. Bare skin around eye pink and blue. Juvenile duller, lacks well defined chestnut tail tips.

Habitat. Tropical deciduous forest and thorn forest in lowlands. Also sometimes in palm plantations and dense mangroves along coast. Present in areas with drier vegetation than *O. poliocephala*, and at lower altitudes, seldom above 1300 m.

Food and Feeding. Fruits of trees.

Breeding. Peak of nesting period apparently Jun in S Sinaloa, with laying also in May and Jul. One nest was 1 m above ground in a small spiny tree c. 3-5 m tall. Usually 3 eggs; chicks are variegated rich brown and buffy white, paler below.

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. Occurs in a variety of habitats, including some severely altered by man, and therefore not considered of immediate conservation concern.

Bibliography. Banks (1990), Davis (1965), Mayr & Short (1970), Moore & Medina (1957), Ridgway & Friedmann (1946), van Rossem (1934a, 1942), Schaldach (1963), Vaurie (1965a).

7. West Mexican Chachalaca

Ortalis poliocephala

French: Ortalide de Wagler German: Graubrustguan Spanish: Chachalaca Pechigris

Taxonomy. *Penelope poliocephala* Wagler, 1830, Mexico.

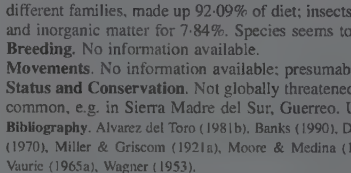

Forms superspecies with *O. wagleri*, which was formerly considered a race of present species; a few cases of hybridization in NW Jalisco were interpreted as evidence of a narrow zone of intergradation in W Jalisco and W Colima, where intermediates were even considered a different subspecies, *lajuelae*; cases of hybridization may have resulted from escapes of imported birds of present species (see page 312). Formerly considered a race of *O. vetula*. In S, range meets those of *O. leucogastra* and *O. vetula*, perhaps with slight overlap; no cases of hybridization known. Monotypic.

Distribution. W Mexico, from S & NE Jalisco and Colima S to CS Chiapas.

Descriptive notes. 62-67 cm; c. 760 g. One of largest *Ortalis*. Tail tips pale buff.

Habitat. Mainly tropical deciduous forests, with rather narrow humidity limits, as avoids rain and cloud forests and does not occur in dry oak-pine forests, except in most humid gullies with luxuriant vegetation. Also sometimes in palm plantations and dense mangroves. In the 2 narrow areas of contact with *O. wagleri* and *O. vetula*, present species found in wetter woodland, reaching higher altitudes, up to 3000 m.

Food and Feeding. Diet based on plant matter, represented by leaves, seeds, flowers and fruits. In one study in Jalisco, plant matter, from 15

different families, made up 92.09% of diet; insects of 3 different families accounted for only 0.006% and inorganic matter for 7.84%. Species seems to be important disperser of seeds.

Breeding. No information available.

Movements. No information available; presumably sedentary.

Status and Conservation. Not globally threatened. Still common in much of range, and locally very common, e.g. in Sierra Madre del Sur, Guerrero. Uncommon in collections, but has been bred.

Bibliography. Alvarez del Toro (1981b), Banks (1990), Davis (1965), Gurrola Hidalgo (1981, 1985), Mayr & Short (1970), Miller & Griscom (1921a), Moore & Medina (1957), Ridgway & Friedmann (1946), Schaldach (1963), Vaurie (1965a), Wagner (1953).

8. Chaco Chachalaca

Ortalis canicollis

French: Ortalide du chaco German: Chacoguan Spanish: Chachalaca Charata
Other common names: Grey-headed Chachalaca (!)

Taxonomy. *Penelope canicollis* Wagler, 1830, Paraguay.

Has hybridized in captivity with *Pipile caninus*. Birds of Paraguayan Chaco have been separated in different race, *ungeri*, but validity doubtful. Two subspecies recognized.

Subspecies and Distribution.

O. c. canicollis (Wagler, 1830) - Chaco in E Bolivia, W Paraguay and N Argentina.

O. c. pantanalensis Cherrie & Reichenberger, 1921 - SW Mato Grosso, Brazil.

Descriptive notes. 50-56 cm; 479-599 g. Head and neck contrast little with colour of back and breast. Immature resembles adult. Race *pantanalensis* browner, less greyish, and larger.

Habitat. Swampy lowland forest and surrounding *mimosa* scrub; frequents borders of trails and edges of groves with dense, close cover. Nominant race also in dry subtropical forest of Andean foothills in Argentina, up to c. 1000 m. Race *pantanalensis* also in semi-deciduous forest, gallery forest, *cerrado* woodland, secondary forest and palm groves, in one study in N Argentina, more abundant in secondary than in pristine woodlands.

Food and Feeding. Leaves, fruits, seeds and flowers; also caterpillars, which can be important in periods of abundance. In one study in N Argentina, herb leaves made up 36.6% of dry mass, fleshy fruits 24.9%, caterpillars 22.1% and flowers and seeds 6.6%. Most popular fruits were those of molle (*Schinus molle*); others included those of mistol (*Zizyphus mistol*), sangre de toro (*Rivina humilis*), coro (*Jodina rhombifolia*), tala (*Celtis pallida*) and tala blanca (*Achatocarpus praecox*). Of flowers, most important were those of garabato (*Acacia*); elsewhere, flowers of *Tabebuia* trees also recorded. All caterpillars were of same species, the mistol butterfly, which abounds in the area in certain years. Leaves and fruits were consumed all year round, with proportion of latter increasing

significantly during wet season. Seeds of fruits are defecated intact, suggesting species is a disperser; apparently, *Schinus polygamus* and *Jodina rhombifolia*, with fruit which ripens in winter, depend on present species for seed dispersion during dry season. Species forages mostly in groups of up to 30 birds, generally in crowns of trees; sometimes on or near ground, especially where undergrowth not too dense.

Breeding. Nov-Feb in N Argentina, during rainy season. Nest is small, simple, shallow platform, loosely built with sticks, stems, tendrils and leaves, without lining; usually situated 2.5-4 m up in dense bush or tree. Lays 3-4 eggs.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. In Brazil, common in all regions of Pantanal, and in less frequented portions of Chaco; probably also in Paraguay. Still common and locally abundant in Argentina, although extensive sections of potential habitat in Chaco have been degraded by overgrazing, wood extraction and fires, resulting in range contraction in several areas, e.g. Tucumán; abundant in El Rey National Park (44,000 ha), NW Argentina, but limited to Chaco habitat and also around buildings of park headquarters; also very common in Pilcomayo National Park (60,000 ha), Formosa. S limit of range in Argentina has shown slight retraction: formerly present S at least to Capilla del Monte, NC Córdoba, but now occurs only in extreme N of province. Relatively common in Bolivian Chaco adjacent to border with Argentina. Persecuted by hunters for food and sport; one hunter recently killed 40 birds in one day in Salta; hunting of species permitted seasonally in Formosa and Tucumán, Argentina. In Bolivia, has no legal protection and is hunted year round, not only by local people but also by hunters coming in organized safaris from Argentina. Commonly kept in captivity locally and in some collections abroad, where is regularly bred.

Bibliography. Bucher (1980), Canevari & Cazzani (1988), Cazzani & Protomastro (1988, 1994), Contino (1980), Dubs (1992), Kerr (1950), Nöres & Yaurieta (1988), Nöres *et al.* (1983), de la Peña (1979, 1992), Pinto (1964), Remsen & Traylor (1989), Sick (1985a, 1993), Vaurie (1964), Wetmore (1926).

9. White-bellied Chachalaca

Ortalis leucogastra

French: Ortalide à ventre blanc **German:** Weibachguan **Spanish:** Chachalaca Ventriblanca

Taxonomy. *Penelope leucogastra* Gould, 1843, no locality.

Formerly considered subspecies of *O. vetula*. Isolated population of *O. vetula* in Costa Rica sometimes assigned to present species. Probably forms superspecies with *O. guttata*, *O. motmot* and *O. supercilialis*. In N, range meets those of *O. poliocephala* and *O. vetula*, perhaps with slight overlap; no cases of hybridization known. Monotypic.

Distribution. Extreme SW Mexico (SE Chiapas), S Guatemala, El Salvador, S Honduras, NW Nicaragua and NW Costa Rica.

Descriptive notes. 43-50 cm; 439-560 g. Brown breast rather abruptly separated from dull white belly. Juvenile like adult, but plumage looser and fluffier.

Habitat. Swampy forest, swamps with coyal palm undergrowth and thick, second growth scrub; also dry forests, pasture or plantation edges and mangrove forests, in lower tropical zone of Pacific slope. Commonest on coastal plain, but also occurs in hills up to c. 1500 m.

Food and Feeding. Mainly berries and fruits, either green or ripe, especially coyal palm dates; also leaves, buds, flowers and some invertebrates. Forages in groups of 6 or more birds,

usually at 6-10 m above ground; seems to come to ground less often than other species of *Ortalis*.

Breeding. Season rather protracted, with records of eggs from Mar to Jul in Guatemala; laying recorded in Apr and May in El Salvador. One record of communal nesting in plantation in Quetzaltenango, Guatemala, with at least 3 nests in adjacent trees. Nest is small, loosely built platform, lined with flattened leaves; placed in tree usually 5-10 m above ground, 2-3 eggs.

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. Still common to locally abundant in much of range; often seen near villages. Has lost habitat through conversion to pastures, sugar cane and cotton fields, but benefited from other alterations implying opening of dense forests; in Guatemala seems to be shifting its altitudinal range higher, as shaded coffee plantations with more open canopy apparently more suitable for species than original broad-leaved forests of lower Pacific slopes. Uncommon in Honduras and N Nicaragua. Uncommon in collections, but has been bred.

Bibliography. Alvarez del Toro (1981b), Dickerman (1987a), Dickey & van Rossem (1938), González (1986), Griscom (1932), Land (1970), Mayr & Short (1970), Miller & Griscom (1921a), Monroe (1968), Moore & Medina (1957), Ridgely & Gwynne (1989), Ridgway & Friedmann (1946), Saunders (1950), Vannini & Rockstroh (1988), Vaurie (1965a), Zepeda (1981).

10. Speckled Chachalaca

Ortalis guttata

French: Ortalide mailée **German:** Tüpfelguan **Spanish:** Chachalaca Moteada

Other common names: Spotted Chachalaca; Colombian Chachalaca (*columbiana*); Brazilian/White-bellied Chachalaca (*araucaum*); Scaled Chachalaca (*squamata*)

Taxonomy. *Penelope guttata* Spix, 1825, Rio Solimes, Brazil.

Forms superspecies with *O. motmot* and *O. supercilialis*, and probably also with *O. leucogastra*. Has been considered conspecific with first two, forming rather dissimilar and geographically disjunct Variable Chachalaca (*O. motmot*). Races *araucaum*, *squamata*, *columbiana* and *guttata* (incorporating *subaffinis*) may merit treatment as four separate species (see page 312). Population of N Colombia has been awarded race *caucaie*, but probably synonymous with *columbiana*; birds of SE Mato Grosso have been ascribed race *remota*, but apparently very similar or identical to *squamata*. Five subspecies usually recognized.

Subspecies and Distribution.

- O. g. columbiana* Hellmayr, 1906 - N & C Colombia.
- O. g. guttata* (Spix, 1825) - E Colombia, E Ecuador, E Peru, N Bolivia and W Brazil.
- O. g. subaffinis* Todd, 1932 - E & NE Bolivia and adjacent Brazil.
- O. g. araucaum* (Spix, 1825) - E Brazil.
- O. g. squamata* Lesson, 1829 - SE Brazil.

Descriptive notes. 45-60 cm; 500-600 g (*columbiana*). Feathers of lower throat and breast conspicuously edged or tipped white or buffy white. Races vary in size, coloration and shape of breast markings.

Habitat. Thickets, grassy slopes, palm groves, interfaces of forest and second growth, and low forests; less often in canopy or at edges of tall forest. In lowlands and foothills of tropical and

subtropical zones, locally up to near transition area with temperate zone, at minimum 2275 m in Bolivia, but up to 2500 m in Colombia and 2700 m in Peru. Race *squamata* mainly occurs from sea-level to 800 m.

Food and Feeding. Virtually no information; often takes catkins of guarumo (*Cecropia*) trees. Usually forages in small flocks.

Breeding. Feb (*columbiana*); one male in breeding condition in Jun (*guttata*); birds in breeding condition in Oct and Nov (*squamata*). Incubation reportedly 21 days.

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. Common in many parts of range, even in densely populated areas; seems to tolerate human activity fairly well. Race *columbiana* extirpated from many parts of its former range; currently localized. Race *guttata* fairly common in Colombia and Brazil, and common in Peru, where is most abundant cracid; in Peru threatened only very locally by habitat destruction for agriculture, and by hunting. Race *subaffinis* recorded daily in small numbers during survey of Río Machariapo dry forest, La Paz, Bolivia, in 1993. Race *araucaum* fairly common in many parts of range, including several reserves and parks. Race *squamata* rather uncommon in Rio Grande do Sul, SE Brazil; population recently discovered on Ilha do Cardoso, São Paulo, although no previous records from this state. Uncommon in captivity, but has been bred.

Bibliography. Bege & Marterer (1991), Belton (1984), Dubs (1992), Eijlsdä & Knabbe (1990), Forrester (1993), Hernández & Rodríguez (1988), Hilly & Brown (1986), Koeppke & Koeppke (1963), Miller (1952), Ortiz, E. & O'Neill (1988), Ortiz, F. (1981), Parker *et al.* (1982), Pearman (1993a), Pinto (1964), Remsen & Traylor (1989), Sick (1985a, 1993), Teixeira & Antas (1981), Vaurie (1965b), Zimmer & Osgood (1930)

11. Little Chachalaca

Ortalis motmot

French: Ortalide motmot **German:** Motmotguan **Spanish:** Chachalaca Motmot

Other common names: Guiana Chachalaca; Rufous-headed Chachalaca (*ruficeps*)

Taxonomy. *Phasianus Motmot* Linnaeus, 1766, Brazil and Guiana = Cayenne.

Forms superspecies with *O. guttata* and *O. supercilialis*, and probably also with *O. leucogastra*. Both *O. guttata* and *O. supercilialis* have been included in present species (see page 313). Race *ruficeps* has recently been considered full species by some authors. Two subspecies recognized.

Subspecies and Distribution.

- O. m. motmot* (Linnaeus, 1766) - S Venezuela, the Guianas and N Brazil, N of R Amazon.
- O. m. ruficeps* (Wagler, 1830) - NC Brazil, S of R Amazon.

Descriptive notes. 43-54 cm; 385-620 g. Chestnut head like *O. garrula* and *O. erythropetra*, but brown, not chestnut, primaries. Race *ruficeps* smaller and darker.

Habitat. Patches of forest with dense undergrowth along rivers or in clearings in more extensive woodlands. Also thick tangled coastal brush and dense second growth. Avoids dense forest. Lowlands up to 1700 m. In French Guiana prefers interface between savanna and forest, and secondary forest near settled areas.

Food and Feeding. Mainly berries and fruits. Usually forages in pairs or small flocks, in trees or on the ground.

Breeding. Records of laying in May, Sept and Dec in Surinam; Nov-Dec, at beginning of rains, in French Guiana. Nest is fairly small cup, made of small roots, flattened leaves and sticks, and lined with leaves; one nest was built on fork of small shrub at c. 2 m above ground, another in a low tree; in French Guiana species said to place nest low in bushes or even on ground. 3 eggs. No further information available.

Movements. No information available; presumably sedentary.

Status and Conservation. Not globally threatened. Considered rather common in Surinam, Guyana and French Guiana; in Brazil fairly common in Amapá, N Roraima, around Santarém (Pará) and around Manaus (Amazonas). Quite common in captivity, where frequently bred.

Bibliography. Forrester (1993), Haverschmidt (1956, 1968), Meyer de Schauensee & Phelps (1978), Pinto (1964), Porras & Arrigaia (1981), Sick (1985a, 1993), Snyder (1966), Strahl & Silva (1988), Teixeira & Antas (1981), Tostian *et al.* (1992), Vaurie (1965b)

12. Buff-browed Chachalaca

Ortalis supercilialis

French: Ortalide à sourcils **German:** Gelbbraueguan **Spanish:** Chachalaca Cejuda

Other common names: Superciliated Chachalaca

Taxonomy. *Ortalis supercilialis* G. R. Gray, 1867, South America.

Forms superspecies with *O. guttata* and *O. motmot*, and probably also with *O. leucogastra*. Has been included, together with *O. guttata*, in *O. motmot* (see page 313). *O. spixi* is a synonym. Monotypic.

Distribution. NE Brazil, S of R Amazon.

Descriptive notes. 42-46 cm. Smallest *Ortalis*, and only one with supercilary streak, which varies individually from buffy white to pale cinnamon.

Habitat. Thickets of scrub and forest, in lowlands.

Food and Feeding. No information available. **Breeding.** Dec-Feb. One nest was a fairly large, flat structure made of dry twigs. 2-3 eggs. No further information available.

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. Fairly common around Belém, Pará, and

scarce in São Luís area, N Maranhão.

Bibliography. Forrester (1993), Pinto (1964), Sick (1985a, 1993), Teixeira & Antas (1981), Vaurie (1965b)

Genus *PENELOPE* Merrem, 1786

13. Band-tailed Guan

Penelope argyrotis

French: Pénélope à queue barrée German: Bindenschwanzguan Spanish: Pava Camata

Taxonomy. *Pipile argyrotis* Bonaparte, 1856, Caracas.

Forms superspecies with *P. barbata*, with which often considered conspecific (see page 313). Race *colombiana* has been considered separate species. Race *albicauda* sometimes merged with nominate. Birds from W Venezuela and N Colombia, and from N Venezuela, sometimes awarded separate races, respectively *mesaeus* and *olivaceiceps*, but differences generally reckoned too slight to merit acceptance. Three subspecies recognized.

Subspecies and Distribution.

P. a. albicauda Phelps & Gilliard, 1940 - Sierra de Perijá, in Colombia and Venezuela.

P. a. colombiana Todd, 1912 - Santa Marta Mts, N Colombia.

P. a. argyrotis (Bonaparte, 1856) - N Colombia and N & W Venezuela.

Descriptive notes. 50-61 cm. Present species and *P. barbata* are only members of genus with tail feathers not uniformly coloured, as they have ill defined rufous, cinnamon or buffy white terminal band. Present species differs from *P. barbata* in conspicuous white markings on the upperwing-coverts, more prominent dewlap and more white on face, especially on the ear-coverts. Plumage of juvenile virtually indistinguishable from that of adult. Race *albicauda* generally similar to nominate but has buffy white tail tips: race *colombiana* has crown feathers edged white and more pointed than in nominate, and has

less white on supercilium.

Habitat. Dense forests in subtropical and upper tropical zones; prefers wet, virgin forest, but at times ventures into tall second growth, coffee plantations and upper edges of drier forest. Often in rugged, mountainous terrain; in Santa Marta Mts occurs at 1000-2000 m, rarely higher; in Venezuela found mainly between 800 m and 2400 m, although also present locally up to 3050 m and as low as 300 m, especially in NE. Favours very wet regions and so is generally commoner on seaward N slope of Venezuelan Cordillera.

Food and Feeding. Fruits, particularly pulpy ones, e.g. those of laurel and guarumo (*Cecropia*) trees; hard seeds are regurgitated. Occasionally comes to ground to take fallen fruit, but usually feeds in middle storey of trees. Drinks water caught in bromeliad leaf bracts, or in flowers of heliconias. Usually feeds in small groups of 3-5 birds, but more may gather at a fruit-laden tree.

Breeding. In Venezuela groups begin to break up, and territories to be established, in Jan; nests Feb-Apr, even May, with torrential rains coming at end of season; chicks in Apr and Jun in Santa Marta Mts, Colombia. Territorial; sometimes several territories close together. Nest is a loosely constructed, unwoven structure made of plant matter, usually placed 1-8 m above ground in trees of Rubiaceae. Chicks are uniform dark brown above, buffy brown and dull white below.

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. Locally common in many areas. Uncommon to fairly common, but infrequently seen, in Colombia, where threatened by deforestation in several areas; in 1990 status in Colombia classed as indeterminate, but probably at least vulnerable, particularly race *colombiana* endemic to Santa Marta Mts, a critical region for conservation. Uncommon in collections, but has been bred.

Bibliography. Carraker (1934), Fjeldså & Krabbe (1990), Hernández & Rodríguez (1988), Hilty & Brown (1986), Koenig (1961), Meyer de Schauensee & Phelps (1978), Porras & Arriaga (1981), Schäfer (1953a, 1954b), Strahl & Silva (1988), Todd & Carraker (1922), Vaurie (1966b).

14. Bearded Guan

Penelope barbata

French: Pénélope barbu German: Bartguan Spanish: Pava Barbuda

Taxonomy. *Penelope barbata* Chapman, 1921, Taraguacocha, Cordillera de Chilla, Ecuador. Often considered a race of *P. argyrotis*, with which forms superspecies (see page 313). Recently suggested to be race of *P. montagnii*. Peruvian population has been awarded separate race, *inexpectata*, but validity doubtful, as distinguishing characters of plumage, especially vermiculated belly, also reported in recent specimens from Ecuador, and may be an immature feature. Monotypic.

Distribution. S Ecuador and adjacent NW Peru.

Descriptive notes. c. 55 cm. Ill defined rufous terminal band in tail; present species and *P. argyrotis* are only members of *Penelope* with tail feathers not uniformly coloured. Differs from *P. argyrotis* by lack of conspicuous white markings on upperwing-coverts, fully feathered chin and upper throat, and partially feathered tarsus.

Habitat. Montane cloud forests, both humid and dry, in temperate and upper subtropical zone of W slope of Andes. Usually between 1500 m and 3000 m, but regularly down to 1200 m in Lambayeque, Peru. Sometimes found in small, relic forest patches.

Food and Feeding. Little information available, but known to feed mainly on fruits. One record of yellowish green fruits of an unidentifiable, probably undescribed, tree in S Ecuador. Large

quantities of undigested seeds in droppings might indicate that present species is important disperser of seeds. Reported to forage mainly in pairs or small groups of 3 or 4 (up to 8) individuals, often on ground.

Breeding. Several records, old and recent, of chicks between Dec and Mar, though in some localities chicks have been recorded in Jun and Jul. No further information available.

Movements. Presumably sedentary. Population in Podocarpus National Park evidently present all year round.

Status and Conservation. VULNERABLE/RARE. Populations only partly protected. Common at end of 19th century in N Peru and probably also in Ecuador until destruction of forest became so widespread. Uncommon in Peru in 1982; probably decreasing, but may still be fairly common in unexplored areas of its range. In Ecuador, where considered most threatened of all montane cracids, in 1989 total population estimated at 500-3000 pairs, probably c. 1500 pairs. Several populations occur in small patches of suitable habitat within larger areas almost devoid of forest. Viable populations in large Podocarpus National Park (S Ecuador), where at least 1000 km² of suitable habitat exists, with estimated density of 1 pair/km²; most of park (99%) was open to mining until 1993, when concession lifted due to international pressure campaign, and only a small part has been mined; casual gold prospectors and settlers, who had already established some dwellings and small-scale logging concerns inside park, are now pushing for access, and pressure likely to increase greatly in future; with some minor extensions, park could also include important populations of present species currently occurring just outside its limits. For protection of present species and several other threatened species, additional montane forest reserves badly needed, e.g. Cordillera de Chilla in Ecuador, and Cerro Chinguela, Ayabaca-Cruz Blanca area and upper valleys of R Sana and R Chanchay in Peru; in 1989, species seen 3 times at 2625 m during 4-day expedition to Ayabaca, where known to be suffering due to habitat destruction through logging in temperate zone, and where intensively hunted for food. In addition to habitat destruction, hunting pressure also blamed for species' decline in many areas; its confiding nature renders it especially vulnerable to this threat. Very rare in captivity; held in 1 collection in Mexico.

Bibliography. (1981), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Rahbek *et al.* (1989), Vaurie (1966b).

15. Baudo Guan

Penelope ortoni

French: Pénélope d'Orton German: Ortonguan Spanish: Pava de Orton
Other common names: Orton's Guan

Taxonomy. *Penelope ortoni* Salvin, 1874, Mindo, western slope of Pichincha, Ecuador. Has been considered a race of *P. montagnii*, but ranges contiguous, with overlap in W Ecuador and possibly also in SW Colombia, without any trace of intergradation, so they probably do not even form a superspecies; apparently closest to *P. marail* (see page 313). Monotypic.

Distribution. W Colombia and W Ecuador.

Descriptive notes. 58-63 cm. The only small *Penelope* without pale markings on head and wings.

Habitat. Humid forests, mainly in upper tropical zone, usually up to 1500 m. W of Andes; perhaps prefers broken country and foothills, but may also occur in lowland forests; in Colombia recorded between 100 m and 1500 m. Absent from dry coastal area of SW Ecuador.

Food and Feeding. No information available.

Breeding. No information available.

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. Currently considered near-threatened. Local in Colombia, where known only from a small number of localities; status in this country stated as vulnerable in 1990. Very rare in captivity; has been kept in one collection in Mexico.

Bibliography. Eley (1979, 1982), Hernández & Rodríguez (1988), Hilty & Brown (1986), Ortiz (1981), Vaurie (1966b).

16. Andean Guan

Penelope montagnii

French: Pénélope des Andes German: Andenguan Spanish: Pava Andina

Taxonomy. *Ortalia montagnii* Bonaparte, 1856, Colombia = El Piñón, above Fusagasugá. Has been considered to include *P. ortoni* as race, but ranges contiguous, with overlap in W Ecuador and possibly also in SW Colombia, without any trace of intergradation, so they probably do not even form superspecies. Population of SE Peru was separated in different race, *marcapatensis*, but later recognized as synonym of *plumosa*. Five subspecies recognized.

Subspecies and Distribution.

P. m. montagnii (Bonaparte, 1856) - NW Venezuela and N & C Colombia.

P. m. atrogularis Hellmayr & Conover, 1932 - W slope of Andes in S Colombia and Ecuador.

P. m. brooki Chubb, 1917 - E slope of Andes in S Colombia and Ecuador.

P. m. plumosa Berlepsch & Stolzmann, 1902 - E slope of Andes in Peru.

P. m. selateri G. R. Gray, 1860 - Yungas of Bolivia; usually said to occur in extreme N Argentina too, but this is based on two specimens recently shown to belong to *P. dabbeni*.

Descriptive notes. 51-61 cm; 818-840 g (*plumosa*). Stocky build, appearing less slender than most other *Penelope*. Throat and tarsus partially feathered, as in *P. barbata*, from which differs by uniformly coloured tail. Juvenile similar, but browner, with indistinctly vermiculated underparts and paler sides of face and throat. Races vary in slight differences of general plumage coloration and in pattern of markings on head and neck.

Habitat. Thick, epiphyte-rich humid forest in mountains, including dwarf forest. In temperate zone up to 3650 m, with one record at 3900 m at Pasco, Peru; occurs at higher altitudes than any other

On following pages. 17. Marail Guan (*Penelope marail*); 18. Rusty-margined Guan (*Penelope superciliosus*); 19. Red-faced Guan (*Penelope dabbeni*); 20. Crested Guan (*Penelope purpurascens*); 21. Cauca Guan (*Penelope perspicax*); 22. White-winged Guan (*Penelope albigularis*); 23. Spix's Guan (*Penelope jacquacu*); 24. Dusky-legged Guan (*Penelope obscura*); 25. White-crested Guan (*Penelope pileata*); 26. Chestnut-bellied Guan (*Penelope ochrogaster*); 27. White-browed Guan (*Penelope jacucaca*).

cracid; also present at times in subtropical mountain zone, as low as 1500 m. Occasionally ventures into tall second growth or open areas with fruiting trees.

Food and Feeding. Mainly fruits in 1-10 mm range. Forages in groups of 3-10 birds, sometimes individually, in middle and upper storeys of fruiting trees.

Breeding. One chick in Mar and a juvenile in Jun in Colombia. Nest is platform made of twigs, lined with leaves. 2 eggs; chicks are dark brown mixed with buff areas, and have an irregular white band along sides of crown.

Movements. Non-migratory, but performs

seasonal movements in search of fruit, sometimes leaving forest to move into second growth or even isolated trees. In Colombia stragglers recorded above and below normal altitudinal range.

Status and Conservation. Not globally threatened. Uncommon to fairly common in Colombia, and fairly common to common in Peru, where extensive inaccessible areas in E Andes suggest species may have healthy populations. Tolerates partly disturbed areas and frequently observed near human populations; survives in small highland forest patches unless persecuted. Considered vulnerable in Argentina by Dirección Nacional de Fauna; however, presence of species in Argentina based on two skins, both recently shown to be *P. dabbeni*. Suffers locally from habitat destruction for wood extraction or agriculture, and from limited hunting for local consumption. Uncommon in collections, but has been bred.

Bibliography. Blake (1962), Canevari & Caziani (1988), Fjeldså & Krabbe (1990), Hernández & Rodríguez (1988), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Olivares (1969), Olrog (1960), Ortiz, E. & O'Neill (1988), Ortiz, E. (1981), Parker *et al.* (1982), de la Peña (1992), Porras & Arriaga (1981), Remsen & Cardiff (1990), Remsen & T aylor (1989), Strahl & Silva (1988), Vaurie (1966b).

17. Marail Guan

Penelope marail

French: Pénélope marail

German: Marailguan

Spanish: Pava Marail

Other common names: Cayenne Guan

Taxonomy. *Phasianus Marail* P. L. S. Müller, 1776, Cayenne.

May form superspecies with *P. supercilialis*; also seems to be close to *P. ortoni* (see page 313). Has hybridized with *P. purpurascens* and *P. pileata* in captivity. Two subspecies recognized.

Subspecies and Distribution.

P. m. marail (P. L. S. Müller, 1776) - the Guianas and E Venezuela S of R Orinoco.

P. m. jacupeba Spix, 1825 - N Brazil and SE Venezuela.

Descriptive notes. 63-68 cm; 770-1015 g. Has greenish olive gloss on back, wings and central tail feathers, and bluish black lateral tail feathers. Race *jacupeba* is slightly smaller, paler and more greyish brown.

Habitat. Heavy tropical forest, especially near water, near coast or inland; less often in second growth. Occurs in lowlands; in Venezuela between 100 m and 600 m. In French Guiana found in pristine forest.

Food and Feeding. Almost exclusively fruit. Diet well studied in French Guiana; quite selective, with only 24 species of plant recorded, and 4 (*Euterpe oleracea*, *Eugenia coffeifolia*,

Guatteria sp. nov., *Minuartia guianensis*) accounting for 75% of all food taken; almost entirely frugivorous, and continues relying on fruits during dry season, when other sympatric, mainly frugivorous species increase their intake of flowers and other plant parts; insects very occasionally taken, representing less than 0.3% of diet. Forages singly or in small groups, mostly in trees, but sometimes on the ground.

Breeding. Laying Oct-Nov in French Guiana. Nest is cup-like; placed high in fork of tree. Lays 2-3 eggs; incubation 29 days (in captivity).

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. Common in many areas, e.g. in Surinam considered common in 1968. Widespread in French Guiana, but considered to be undergoing marked decline in areas with heavy hunting pressure. In Brazil fairly common in Amapá, N Rondônia and around Manaus, Amazonas. Uncommon in collections, but has been bred.

Bibliography. Amadon (1979), Eley (1979), Forrester (1993), Haverschmidt (1968), Meyer de Schauensee & Phelps (1978), Pinto (1964), Porras & Arriaga (1981), Sick (1985a, 1993), Snyder (1966), Strahl & Silva (1988), Théry *et al.* (1992), Thibault & Guyot (1988), Tostain *et al.* (1992), Vaurie (1964).

18. Rusty-margined Guan

Penelope supercilialis

French: Pénélope péoa

German: Weistiringuan

Spanish: Pava Yacupemba

Other common names: Superciliated/White-eyebrowed Guan

Taxonomy. *Penelope supercilialis* Temminck, 1815, state of Pará, Brazil.

May form superspecies with *P. marail*. Has hybridized in captivity with *P. purpurascens*, *P. pileata* and *Pipile cuman*. Recently, two new races have been described from the headwaters of the Mamé River, Amazonas (*cyanosparius*), and the coast of Alagoas and Pernambuco (*alagoensis*), but the types and paratypes are of captive origin. Three subspecies usually recognized.

Subspecies and Distribution.

P. s. supercilialis Temminck, 1815 - NC & E Brazil, S of Amazon S to Maranhão.

P. s. jacupemba Spix, 1825 - E Bolivia (Santa Cruz) and C & S Brazil.

P. s. major Berton, 1901 - extreme S Brazil (Santa Catarina, Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).

Descriptive notes. 55-73 cm; 950-1150 g (*superciliaris*), 750-880 g (*jacupemba*). Pale supercilium, black earcoverts and chestnut-orange edgings of inner wing feathers. Immature very similar to adult. Races vary in size, tone of general coloration and broadness and tone of wing feather fringes; supercilium also differs, in *jacupemba* being very distinct and often ochraceous or rich buff, rather than white.

Habitat. Heavy forest, forest borders, gallery forest, *capoeira*, forest groves in *cerrado* woodlands, *caatinga*, river and lake edges. Usually in lowlands; recorded at 1100 m at Serra do Japi, São Paulo.

Food and Feeding. Mainly fruits, including those of bicuiba (*Virola*), sapacaiá (*Lecythis*), murici (*Byrsonima*), aricanga palm (*Geonoma*), guarumo (*Cecropia*), *Schinus*, *Psidium*, *Syagrus* and *Byrbiuba*; fruits of two exotic species, *Coffea arabica* (Africa) and *Eriobotrya japonica* (Asia), also found to constitute important part of diet in São Paulo; in this study, present species was considered to be

non-specialized frugivore, both in terms of species and size of fruits taken; some insects occasionally taken, both adults (Hymenoptera, Coleoptera) and larvae (Lepidoptera). Although primarily arboreal, occurring at variable levels, is often recorded feeding on ground. Forages singly, in pairs, or in groups of up to 10 birds.

Breeding. Oct-Feb in N Argentina. Nest is a platform of twigs, lined with leaves and stems, located in a tree. Lays 3 eggs; incubation 28 days (26-27 in captivity).

Movements. Sedentary. In study at several sites in São Paulo, daily altitudinal movements detected, involving vertical differences of up to 400 m: in Mata do Pau Furado and in Serra do Japi, birds usually spend night in highest parts and move down to feed in lower parts.

Status and Conservation. Not globally threatened. Nominate race has apparently declined in many parts of range; not recorded since at least 1960 from around Belém and Santarém, Pará; scarce in Amazônia (Tapajós) National Park, Pará. Race *jacupemba* still fairly common in many parts of range, including several national parks, but has been extirpated or has declined considerably in others; occurs with small, isolated populations in São Paulo; reported to be rare in the Poconé region (Pantanal), Mato Grosso. Race *major* has a very restricted distribution in Argentina; currently frequent in Iguazú National Park (55,000 ha), Misiones, especially in the core area, where birds are quite tame; also present in Uruguá-i Provincial Park, Misiones, where 4-5 birds seen in 1985; unrecorded recently in other areas of Argentina, although Arroyo Aguarray-Guazú region, where the species was common at least until 1940's, has not been surveyed in recent times. Collected in Rio Grande do Sul, S Brazil, up to end of 19th century, but no recent records. Despite legal protection, known to be hunted in N Argentina. Uncommon in collections, but has been bred.

Bibliography. Bege & Marer (1991), Belton (1984), Canevari & Caziani (1988), Chebez (1990), Cintra & Yamashita (1990), Dubs (1992), Eley (1979), Forrester (1993), Guix (1994), Kuhlman (1946), Nardelli (1993), Neumann (1933), Nores & Yzurieta (1988), de la Peña (1992), Pinto (1964), Remsen & T aylor (1983, 1989), Sick (1970, 1985a, 1993), Taibel (1953), Teixeira & Antas (1981), Vaurie (1966b).

19. Red-faced Guan

Penelope dabbeni

French: Pénélope de Dabbene

German: Rotgesichtguan

Spanish: Pava Carirroja

Other common names: Dabbene's Guan

Taxonomy. *Penelope dabbeni* Hellmayr and Conover, 1942, Cerro de Calilegua, Ledesma, Jujuy, Argentina.

Usually regarded as an isolated relative of *P. obscura*, although sometimes considered to be more closely related to *P. montanii*. *P. nigrifrons* is a synonym. Monotypic.

Distribution. S Bolivia (S Santa Cruz, Chuquisaca and Tarija) and NW Argentina (Jujuy and Salta).

Descriptive notes. 63-69 cm; one bird 1230 g. Only species of *Penelope* with bright red bare facial skin.

Habitat. Large tracts of cloud forest on slopes of E Andes, with presence of large trees, e.g. cedars (*Cedrela*), *Eugenia* or *Blepharocalyx*; in highest parts of range forest is dominated by alders (*Alnus*). Found mainly between 1800 m and 2500 m; occasionally as low as 800 m, or as high as 2700 m.

Food and Feeding. No information available on diet. Forages mainly in trees; usually in pairs, but a group of c. 25 birds recently reported from Bolivia.

Breeding. Displaying and calling pairs recorded in Sept-Oct in Bolivia. Nest is a platform made of twigs and stems, lined with leaves, placed in a tree. 3 eggs.

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. Currently considered near-threatened. Scarce and local. In Argentina, common in Calilegua National Park (76,000 ha), Jujuy, where relatively well protected, more by inaccessibility and isolation than by adequate wardening. Only other confirmed reports of recent occurrence of species in Argentina are 3 specimens collected in 1976 at Río Lipeo and Los Toldos, Salta. Species may also be present in the isolated Baritú National Park (72,000 ha), Salta, which lies within its range, but there are no records. Considered vulnerable in Argentina by Dirección Nacional de Fauna. Any populations outside national parks probably suffer hunting pressure. In Bolivia, species had not been recorded during recent decades and considerable reduction of its habitat has been reported in O'Connor and Arce Provinces, Tarija. However, in 1991, a sizeable population was discovered in C Chuquisaca, with density of c. 5 pairs/km², and estimated total of 3000 pairs; a few birds were also seen near Vallegrande, S Santa Cruz, indicating a range extension to N; a population of similar size may inhabit an area N of R Pilcomayo. The population discovered in Chuquisaca was not suffering severe hunting pressure, and at present benefits from absence of roads in the area.

Bibliography. Bond & Meyer de Schauensee (1942/43), Canevari & Caziani (1988), Collar & Andrew (1988), Fjeldså & Krabbe (1990), Fjeldså & Mayr (1994), Nores & Yzurieta (1988), Olrog (1960, 1984), de la Peña (1992), Remsen & T aylor (1989), Vaurie (1966b).

20. Crested Guan

Penelope purpurascens

French: Pénélope panachée

German: Rostbauchguan

Spanish: Pava Cojolita

Other common names: Purple/Purplish Guan

Taxonomy. *Penelope purpurascens* Wagler, 1830, Mexico.

Forms superspecies with *P. perspicax*, *P. albipennis*, *P. jacquacu* and *P. obscura*. *P. cristata* is a synonym. Has hybridized with *P. marail*, *P. pileata* and *P. superciliosa* in captivity. *P. jacquacu* formerly considered race of present species, but tracheal morphology is different (see page 319). Three subspecies recognized.

Subspecies and Distribution.

P. p. purpurascens Wagler, 1830 - NW & NE Mexico S to Honduras and Nicaragua.

P. p. aequatorialis Salvadori & Festa, 1900 - S Honduras and Nicaragua S to NW Colombia and SE Ecuador; possibly also to extreme N Peru.

P. p. brunescens Hellmayr & Conover, 1932 - N Colombia to E Venezuela.

Descriptive notes. 72-91 cm; 1620-2430 g. Largest member of genus. Has bushy crest, which is often erected, and conspicuous white fringes on foreneck and breast feathers. Juvenile similar to adult, but wing and tail feathers washed with rufous brown, and mottled with blackish brown. Nominative race has white edges on scapulars and mantle feathers, and is larger and less rufescent than the two other races; *aequatorialis* is similar to *brunescens*, but less rufous, especially on the rump and central rectrices.

Habitat. Generally in humid forest and forest borders of tropical and lower subtropical zones; more often in lowlands or hilly areas below 1000 m, but locally or seasonally up to 2300 m or even 3000 m; in Darién, E Panama, commonest up to 1000 m and in smaller numbers to 1450 m. Occasionally ventures into gallery forest, e.g. in Venezuela or N Colombia. Locally found in some drier habitats, e.g. in oak-sweetgum and beech forest in Tamaulipas, NE Mexico, or in humid pine-oak forest in Colima, WC Mexico; absent from open savannas.

Food and Feeding. Berries, figs and other fruits, including those of *Spondias*, *Bumelia*, *Gutteraria*, *Chione*, *Cecropia* and wild papaya; known to be one of the dispersers of wild nutmeg (*Viola surinamensis*), seeds of which it regurgitates. Also consumes seeds, leaves, young shoots and flowers; occasionally takes insects, such as beetles, from ground. Forages singly, in pairs, or in groups of up to 8 birds, usually in high branches of trees; sometimes comes to ground to pick up fallen fruits or scratch for seeds, or to drink.

Breeding. Mar-Jun in Mexico and in Costa Rica; during rainy season in Panama, with chicks in Feb-Mar; Mar-May in N Colombia; Mar-Jul in Venezuela. Nest is a rather bulky platform of twigs and sticks, lined with leaves, placed in a tree well above the ground, or occasionally on top of a stump. Usually 2 eggs, but 3 also recorded; chicks are rich chestnut above mottled buff and black, with reddish brown breast and flanks and white belly. Sexual maturity probably at 2 years old.

Movements. Sedentary, although some seasonal altitudinal movements may occur in mountainous regions.

Status and Conservation. Not globally threatened. Fairly common in Guatemala, especially on Caribbean slope; still persists in fair numbers in areas of Pacific slope where *Crax rubra* has long since disappeared. Maintains stable populations throughout vast areas in Nicaragua. In Costa Rica has disappeared from deforested country and is becoming rare in unprotected forests. Still fairly common in Panama, in areas where hunting pressure is not too great; commoner on Caribbean slope, while on Pacific slope seems to be restricted to a few areas; in 1989 was considered virtually extirpated from Chiriquí Province; well protected in Barro Colorado Biological Reserve. Heavily hunted for food and sport, although often remains in suitable areas after hunting has led to disappearance of larger sympatric *Crax rubra*; in some rural areas of Panama, especially in Darién, sold for food in local markets. Most common species of *Penelope* in captivity in Europe and North America; frequently bred. CITES III in Honduras.

Bibliography. Alvarez del Toro (1981b), Belterman & de Boer (1990), Dickerman (1987a), Eley (1979, 1982), Fjeldså & Krabbe (1990), González (1986), Griscom (1932), Hernández & Rodríguez (1988), Hilly & Brown (1986), Howe & Vande Kerkhove (1980), Land (1970), Leopold (1959), Lowery & Dalquest (1951), Meyer de Schauensee & Phelps (1978), Mondragón & Baez (1981), Monroe (1968), Ortega & Aragón (1981), Ortiz (1981), Porras & Arriaga (1981), Ridgely & Gwynne (1989), Ridgway & Friedmann (1946), Rowley (1984), Saunders (1950), Schudach (1963), Slud (1964), Smith (1966), Stiles & Skutch (1989), Strahl & Silva (1988), Taibel (1955, 1957), Vannini & Rockstroh (1988), Vaurie (1966a), Wetmore (1965), Zepeda (1981).

21. Cauca Guan

Penelope perspicax

French: Pénélope de Cauca

German: Caucaguan

Spanish: Pava del Cauca

Taxonomy. *Penelope perspicax* Bangs, 1911, San Luis, Bitaco Valley, western Colombia.

Has long been considered a race of either *P. jacquacu* or *P. purpurascens* (see page 313). Forms superspecies with these two and also *P. albipennis* and *P. obscura*. Monotypic.

Distribution. W Colombia, on both slopes of W Andes and W slopes of C Andes; almost wholly confined to middle and upper Cauca Valley. Much rarer on W slopes of W Andes, where seen mainly in low passes.

Descriptive notes. c. 76 cm. Back, rump, wings, belly and tail mainly rich chestnut; belly and thighs have some inconspicuous darker markings. Outer tail feathers darker than those of centre.

Habitat. Humid forest in upper tropical and subtropical zones, between 1300 m and 2100 m. Occurs both in primary forest and second growth, and even in groves near tracks.

Food and Feeding. Habits presently under study in protected areas where species survives. Forages in flocks of up to 16 birds, from low trees and shrubs almost to canopy, mainly 3-20 m above ground level.

Breeding. One egg collected in May, but this record is unsatisfactory as well outside range; one juvenile, one third grown, collected in Mar. Two nests recorded, both with 2 eggs. No further information available.

Movements. No information available; presumably sedentary.

Status and Conservation. RARE. Populations largely protected, but vigilance needed. Considered not uncommon at beginning of 20th century, but much scarcer since then, as a result mainly of habitat loss. Before mid 1980's, scarcity of recent records and almost complete destruction of

forest in middle Cauca Valley led to belief that species was possibly extinct, or very nearly so. However, recent observations and the capture of live birds show that small but stable populations still remain, at least in a few areas. Density in Ucumari Regional Park apparently quite high, with 16 birds counted over 2 days in 1990. Also receives protection in Bosque de Yotoco Reserve, where squatters have been effectively excluded; rare in Munchique National Park, although extensive forest remains. Although forest destruction is main threat, hunting has probably also contributed to decline of species; poaching is widespread in Ucumari Regional Park and Munchique National Park.

Bibliography. Collar & Andrew (1988), Collar *et al.* (1992), Eley (1982), Hellmayr & Conover (1932), Hernández & Rodríguez (1988), Hilly & Brown (1986), King (1978/79), Negret (1991), Vaurie (1966a).

22. White-winged Guan

Penelope albipennis

French: Pénélope à ailes blanches

German: Weischwingenguan

Spanish: Pava Aliblanca

Taxonomy. *Penelope albipennis* Taczanowski, 1877, near Tumbes, Peru; type from Santa Lucia. Forms superspecies with *P. purpurascens*, *P. perspicax*, *P. jacquacu* and *P. obscura*. Probably closely related to *P. purpurascens* or *P. jacquacu* (see page 314), but specific status now warranted; validity as species questioned in past, with suggestions that it had been described from a partially albinistic specimen of *P. orioni* or *P. purpurascens*, or that it constituted a morph or variant of one of these species. Monotypic.

Distribution. Extreme NW Peru; recent records only from Lambayeque; historically, also occurred in Tumbes and Piura, where some populations may persist. Original range supposed to extend N to near border with Ecuador, and S to R Chicama, La Libertad. Might also be present in large swampy area bordering Gulf of Guayaquil, in SW Ecuador.

Descriptive notes. c. 70 cm. Only *Penelope* with white primaries (eight outer primaries) and bright blue bill with blackish tip. Also has purplish blue bare skin around eye and large dewlap, with two lobes, deep orange rather than red.

Habitat. Localities currently known to be occupied are on slopes and ravines covered with dry deciduous forest in foothills of W Andes, mainly between 300 m and 900 m, sometimes up to 1200 m. Valleys with permanent streams, safe cover, food plants and little human disturbance; seems to prefer wettest parts, especially during dry season; valleys without permanent water can be visited temporarily. Has also occurred in coastal gallery forest, e.g. on islands in delta of R Tumbes with trees characteristic of dry forest, and densely fringed with mangroves.

Food and Feeding. Mostly plant matter of different kinds, varying throughout year according to cycles of species consumed. Fruits of fig trees (*Ficus*) are particularly favoured when ripe; other fruits include berries of *Celtis iguanea*, drupes of *Geoffroea striata*, and pods of *Pithecellobium*, *Prosopis*, *Acacia*, *Caesalpinia*. Flowers can be eaten whole (*Encelia*) or only petals (*Ervithina*). Also feeds on buds (*Encelia*, *Alternanthera*), leaves (*Encelia*) and seeds, extracted mainly from fruit of *Celtis trichistandra*. Shoots of maize, sweet potatoes and beans taken during occasional visits to fields in Apr, while coffee fruits have been recorded only in one area. Possibly a few insects also eaten. Main food in coastal habitats (Condessa I, Tumbes), at least in Jan-Feb, were berries of buckthorn (*Scutia spicata*), apparently supplemented with pods of mesquite (*Prosopis chilensis*). Drinks early in morning, usually at valley bottom. Usually forages in pairs or small family groups, or in groups of up to 10 birds during non-breeding season.

Breeding. One nest with eggs found in May in Lambayeque, and one old record of chicks in Jan in coastal Tumbes. Only confirmed nest of species was a structure made of twigs and leaves, some still green, situated 2.5 m up a small tree in dense forest; old record of nest, loosely composed of dry sticks and placed c. 3 m above ground, not confirmed to refer to present species. Nest in Lambayeque had 3 infertile eggs. Chicks have yellowish and black down above, paler below.

Movements. Mainly sedentary, but some local movements known. Thought to be merely vagrant in at least 4 of localities where recently recorded. Movements may have certain seasonality, mainly related to rains; birds known to concentrate in evergreen thickets at height of dry season; only known to visit Jagway Grande in Jul-Dec.

Status and Conservation. ENDANGERED. Situation critical: action urgent. Presumed extinct shortly after its discovery in 1876 and for a whole century thereafter, until rediscovered in 1977. Recent records from some 26 localities, of which at least 17 are suspected to hold breeding pairs; population reckoned to be very small at each site, with only 1-4 pairs. Many other valleys in same area have been surveyed and found not to hold species, and the discovery of many other populations within current range is unlikely. Total population at time of rediscovery estimated to number a few hundred birds or possibly fewer than 100, with a minimum of 54-68 counted; in late 1980's under 200 were observed and total population now estimated to be a few hundred. Population seems to have declined recently, notably after land reforms of 1968, which permitted public access to much land previously belonging to large estates. Main threat nowadays is habitat destruction, with trees being felled for charcoal or wood and establishment of new areas of cultivation. Hunting with firearms or slings is another threat, especially in some places; identified as sole cause of extinction around Tumbes between 1850 and 1877; hunting pressure along coast also suspected as main reason for apparent restriction of species to Andean foothills. After rediscovery of species, RARE and WCI have funded research and conservation of species; species and habitat now legally protected, although apparently not effectively; reserve at Quebrada Negrohuasi has also been created within current range. Species not recorded by 1989 expedition to Sozoranga Mts, S Ecuador. Captive breeding centre near Olmos, financed by Stichting Crax, held 23 birds and 4 breeding pairs in 1990; long-term aim is reintroduction of species into natural habitats.

23. Spix's Guan

Penelope jacquacu

French: Pénélope de Spix

German: Spixguan

Spanish: Pava Amazónica

Other common names: White-browed Guan(?); Green-backed Guan (*granti*)

Taxonomy. *Penelope jacquacu* Spix, 1825, "in sylvis fl. Solimões".

Has been considered conspecific with *P. obscura*, and formerly with *P. purpurascens*, but tracheal morphology different (see page 319). Forms superspecies with *P. purpurascens*, *P. perspicax*, *P. albipennis* and *P. obscura*. Race *granti* has been considered separate species, including *orienticola* as race, but there is extensive intergradation throughout present species. Has hybridized with *P. pileata* in captivity. Four subspecies recognized.

Subspecies and Distribution.

P. j. granti Berlepsch, 1908 - Guyana and adjacent E Venezuela S of R Orinoco.

P. j. orienticola Todd, 1932 - SE Venezuela and NW Brazil N of R Amazon and R Solimes.

P. j. jacquacu Spix, 1825 - Amazonia S of R Amazon and R Solimes in W Brazil, E Colombia, E Ecuador, Peru and N Bolivia.

P. j. speciosa Todd, 1915 - C & E Bolivia.

Descriptive notes. 66-76 cm; male 1242-1360 g (*jacquacu*), 1400-1778 g (*orienticola*); female 1142 g (*jacquacu*), 1270-1716 g (*orienticola*). Coloration of races *jacquacu* and *granti* markedly different. Nominate has bronzy olive green upperparts and bright rufescent underparts from lower foreneck to undertail-coverts. Race *granti* somewhat larger and much darker overall, with bluish green gloss on upperparts; easily distinguished from *P. obscura* by pale red legs. Race *speciosa* similar to nominate, but has more white on forehead, supercilium and ear-coverts. Race *orienticola* intermediate between *granti* and nominate in both size and coloration.

Habitat. Humid rain and cloud forest, including both *terra firme* and seasonally flooded forest. Also in forest borders, slashed clearings with scattered trees and gallery forest. In tropical zone; locally in lower subtropical zone. In Venezuela between 100 m and 1800 m; in Colombia, in lowlands and foothills at E base of Andes, up to 500 m; at any altitude, up to 1500 m, in Peru. **Food and Feeding.** Small fruits (e.g. of palms) and seeds have been found in gizzards of collected birds; apparently prefers ripe, soft fruit. Forages singly, in pairs or in small family groups, mainly in middle and top strata of trees; seldom descends to ground.

Breeding. Mostly Jan-Apr in NE Venezuela; one nest in Apr and one male in breeding condition in Aug in Colombia; said to begin in Aug-Sept in Peru. One nest was made mostly of leaves and situated in a tree c. 5 m above the ground. 2 eggs (in captivity).

Movements. No information available; presumably sedentary.

Status and Conservation. Not globally threatened. Common in many parts of range, except in densely populated areas or where forest has been destroyed. In populated areas seems to have changed its habits, becoming shyer, and is often heard although very rarely seen; has managed to survive near Iquitos, Peru. In Peru, where usually regarded as common, reported to be rare along R Napo and in Coshipata Valley, and feared to have been extirpated in parts of Huallaga and Ucayali Valleys due to conversion of habitat for agriculture. In Ecuador, still common in undisturbed forests, with estimated density of 8-2 birds/km² in river edge forests. In Brazil, fairly common in many parts of range, including N Roraima, Pico da Neblina National Park and around cities of Manaus and Tefé (Amazonas) and around R Branco; also fairly common in Acre and Rondônia. Hunted for local food consumption in many parts of range, and locally for commercial purposes. Effective protection in Tambopata Reservation Area, Peru, has led to marked recovery of population, with threefold increase in numbers over 10 years. Quite common in captivity, where frequently bred.

Bibliography. Conover & Phelps (1947), Eley (1979, 1982), Forrester (1993), Hernández & Rodríguez (1988), Hilty & Brown (1986), Johnson (1993), Meyer de Schauensee & Phelps (1978), Olivares & Hernández (1962), Ortiz, E. & O'Neill (1988), Ortiz, F. (1981), Parker *et al.* (1982), Pinto (1964), Porras & Arriaga (1981), Remsen & T aylor (1989), Sasaki *et al.* (1982), Sick (1965, 1985a, 1993), Snyder (1966), Strahl & Silva (1988), Terborgh & Weske (1975), Vaurie (1966a), Willard *et al.* (1991).

24. Dusky-legged Guan

Penelope obscura

French: Pénélope yacouhou

German: Bronzeguan

Spanish: Pava Oscura

Other common names: Dusky/Common Guan

Taxonomy. *Penelope obscura* Temminck, 1815, Paraguay, ex Azara.

Has been considered conspecific with *P. jacquacu*, but tracheal morphology is different (see page 319). Forms superspecies with *P. purpurascens*, *P. perspicax*, *P. albipennis* and *P. jacquacu*. Three subspecies recognized.

Subspecies and Distribution.

P. o. bronzinga Hellmayr, 1914 - E Brazil (Espírito Santo to Santa Catarina).

P. o. obscura Temminck, 1815 - SE Paraguay, NE Argentina, Uruguay and extreme S Brazil (Rio Grande do Sul).

P. o. bridgesi G. R. Gray, 1860 - C Bolivia S to NW Argentina, on E slope of Andes.

Descriptive notes. 68-75 cm; 960-1200 g. Only member of genus with dark legs; overall plumage and bare facial skin also dark. Races vary in size, tone of general coloration and markings. Nominate race is darkest and smallest, with well developed whitish streaks only on foreneck and breast; race *bronzinga* has more conspicuous white edges on feathers of head, forming well developed supercilium; race *bridgesi* largest, with prominent purer white streaks on neck and breast, and also on scapulars and wing-coverts, but supercilium faint or absent.

Habitat. Tall forest, gallery forest, small river islands with forest surrounded by grassland; also in montane forest up to 2200 m, where lower country is too dry for evergreen forest, or forest has been destroyed; sometimes ventures into scrub and agricultural land. May be scarce in densest forests, perhaps due to abundance of mammalian predators and preference for feeding on ground. In El Rey National Park, NW Argentina, commonest below 1000 m, especially in ecotones between Chaco woodland and denser, more humid forest. Race *bridgesi* in Bolivia most often found at higher altitudes, especially in N of range, where approaches that of *P. jacquacu*.

woodland patches and second growth in lowlands and foothills of tropical and upper tropical zones; also in montane forest up to 2200 m, where lower country is too dry for evergreen forest, or forest has been destroyed; sometimes ventures into scrub and agricultural land. May be scarce in densest forests, perhaps due to abundance of mammalian predators and preference for feeding on ground. In El Rey National Park, NW Argentina, commonest below 1000 m, especially in ecotones between Chaco woodland and denser, more humid forest. Race *bridgesi* in Bolivia most often found at higher altitudes, especially in N of range, where approaches that of *P. jacquacu*.

Food and Feeding. Fruits, including those of *Eugenia uruguayensis*, *Citharoxylum montevidense*, *Rapanea lorentziana*, *Didymopanax*, *Calyptanthus* and *Croton*; also those of certain palms, which are apparently favourite food in Paraguay; recorded invading poultry yards to feed on corn in Rio Grande do Sul; study in São Paulo suggests species is rather specialized frugivore. In El Rey National Park, NW Argentina, birds feed mainly on leaves, complemented with available fruit during winter; mostly fruits in Nov-Mar (wet season); seeds also found in droppings, indicating species may be important as disperser of seeds. Forages singly, in pairs or in small parties, usually up to 6 birds, although as many as 30 recorded; mainly in trees, especially in lower and middle storeys, but often on ground. Drinks at dawn at rivers, pools or forest streams.

Breeding. In NW Argentina pair formation in Nov and chicks in early Jan (*bridgesi*); one half-grown juvenile seen with adult in Jan in Rio Grande do Sul (*obscura*). Nest is cup-like, made of twigs and stems, lined with leaves, situated in a tree, usually well hidden in dense tangle of vegetation, c. 3 m above ground. Usually 2-3 eggs (up to 4); can lay two clutches in same year; incubation c. 28 days.

Movements. Presumably sedentary, but in NW Argentina (*bridgesi*) may use of different vegetation levels throughout year. No further information available.

Status and Conservation. Not globally threatened. Race *bronzinga* has declined drastically in state of São Paulo, Brazil, and was considered globally vulnerable in 1990 by ICBP/IUCN International Cracidae Specialist Group. Nominate race said to survive in substantial numbers in Uruguay, especially in thick woodlands of N; also in many areas of Rio Grande do Sul, Brazil, which has been considered as indication that illegal hunting for food or sport by locals is not a significant threat there; fairly common in several protected areas, e.g. Aparados da Serra National Park, Rio Grande do Sul, and Iguacu National Park, Paraná. Recently said to be local and generally scarce in N Argentina, where known to be common during 19th century; 4-5 pairs seen in 1985-1986 in Reserva El Bagual (Presidente Irigoyen), Formosa, and minimum 30 birds estimated in c. 1000 ha of islands in Paraná Delta, Buenos Aires, where surrounding habitat is being rapidly deforested or converted into plantations; recently seen in secondary forest. Race *bridgesi* abundant in El Rey National Park (44,000 ha), NW Argentina, where seen in all habitats, but outside park closely tied to montane forest, which is less altered than Chaco and pre-montane forests in region. Also present in Baritú National Park (72,000 ha), Salta, and Calilegua National Park (76,000 ha), Jujuy; both parks have little vigilance, but inaccessibility and isolation provide protection. Much reduced, with several local extinctions, in Tucumán and in populated areas in general, due to habitat alteration and hunting. Considered vulnerable in Argentina by Dirección General de Fauna, and said to be decreasing in numbers except in a few national parks; both races in this country intensively hunted for food and sport, despite legal protection. Kept and bred in captivity locally and in a few collections abroad.

Bibliography. Bege & Marterer (1991), Belton (1984), Brown, A. (1986), Canevari & Cazzani (1988), Caviglia (1981), Césari & Domínguez Alonso (1974), Dinelli (1929), Eley (1979, 1982), Forrester (1993), Gore & Gepp (1978), Guix (1994), Guix *et al.* (1992), Kuhlman (1946), Nogueira Neto (1973), Nores & Yzurietta (1988), de la Peña (1992), Pinto (1964), Remsen & T aylor (1989), Scott & Brooke (1985), Sick (1985a, 1993), Teixeira & Antas (1981), Vaurie (1966a).

25. White-crested Guan

Penelope pileata

French: Pénélope à poitrine rousse German: Weischopfguan Spanish: Pava Crestiblanca

Other common names: White-headed/Green-backed/Pileated Guan

Taxonomy. *Penelope pileata* Wagler, 1830, state of Pará, Brazil.

Forms superspecies with *P. jacquacu* and *P. ochrogaster*, and all three once considered conspecific. Has hybridized in captivity with, at least, *P. superciliosus*, *P. marail*, *P. jacquacu*, *P. jacquacu* and *P. purpurascens*, and even with *Crax alberti*, Montepic.

Distribution. NC Brazil, in relatively small area S of R Amazon, from lower R Madeira to lower R Tapajós.

Descriptive notes. 75-82.5 cm; 1100-1600 g. Most colourful member of genus, with marked contrast between glossy dark greenish olive on most of upperparts and rich chestnut rufous on underparts. Rufous hindneck and upper mantle, contrasting with rest of mantle, back, wings and tail, clearly distinguish present species from *P. ochrogaster*; also has more black on face, especially on ear-coverts. Juvenile similar to adult, but duller, with paler eye.

Habitat. Forest in lowlands; seems to occur exclusively in rather dense forest, although general ecology still poorly known.

Food and Feeding. No information available.

Breeding. Lays 4 eggs in captivity, although 3 probably commoner; chicks have upperparts patterned with dark brown, ashy grey, yellowish grey and blackish. No further information available.

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. Currently considered near-threatened. Apparently confined to heavy forest. Fairly common in Amazonia (Tapajós) National Park; scarce around Santarém, Pará. Uncommon in collections, but has been bred, e.g. in Sorocaba Zoological Park, Brazil, and Cracid Breeding and Conservation Centre in Lanaken, Belgium.

Bibliography. Eley (1979), Forrester (1993), Pinto (1964), Rutgers & Norris (1970), Sick (1965, 1985a, 1993), Taibel (1957), Vaurie (1966b).

26. Chestnut-bellied Guan

Penelope ochrogaster

French: Pénélope à ventre roux

German: Rotbrustguan

Spanish: Pava Ventrirrufo

Taxonomy. *Penelope ochrogaster* Pelzeln, 1870, nas Frechas and Engenho do Pari, near Cuyabá, Mato Grosso.

Forms superspecies with *P. jacquacu* and *P. pileata*, and all three once considered conspecific. Monotypic.

Distribution. Scattered localities in C Brazil, from Goiás to W Minas Gerais and S Mato Grosso. Possibly also to be found in adjacent areas of Bolivia, where appropriate habitat of species is widespread.

Descriptive notes. 67-5-75 cm. Recalls *P. pileata*, but plumage less contrasted, mainly because upperparts paler; hindneck of same general colour as rest of upperparts; browner ear-coverts. Black band bordering bare facial skin and throat, and richer rufous underparts, distinguish present species from *P. jacquacu*.

Habitat. Typically occurs in swampy woods of deciduous trees and also savannas, in lowlands. Probably prefers heavily wooded areas along rivers or in swamps; also inhabits mixed areas of forest interspersed with savanna or *campo*. Preferred habitat in Poconé

region, Mato Grosso, is semi-deciduous gallery forest growing on higher terrain that is rarely flooded; during the dry season these areas generally have a heavy covering of leaf litter on the ground.

Food and Feeding. Virtually no information available. Recorded feeding on the flowers of a *Tubebuia* tree.

Breeding. Clutch size recorded as consisting of 2 eggs. No further information available.

Movements. No information available, but presumably sedentary.

Status and Conservation. VULNERABLE/RARE. Populations only partly protected. Has been considered very rare; in contrast, some authorities state species to be uncommon, but not particularly threatened. Very few specimen and sight records, suggesting low population size, or at least that species is either highly localized or highly secretive. Rarest cracid in semi-deciduous forest in the Pantanal; appears to be moderately common around Poconé, Mato Grosso, where hunting pressure is relatively limited; not recorded since at least 1960 from Barranquinho, SW Mato Grosso. No threats definitely known, but species is presumably hunted for food and probably suffering some habitat loss, given considerable agricultural development occurring within its range. Occurs within Araguaia National Park, and at least around periphery of Pantanal National Park. Very rare in captivity.

Bibliography. Cintra & Yamashita (1990), Collar & Andrew (1988), Collar *et al.* (1992), Dubs (1992), Eley (1979), Naumburg (1930), Pinto (1952a, 1964), Pinto & de Camargo (1952), Sick (1985a, 1993), Vaurie (1966b).

27. White-browed Guan

Penelope jacucaca

French: Pénélope à front blanc

German: Weibrauenguan

Spanish: Pava Yacucaca

Other common names: Brown Guan

Taxonomy. *Penelope jacu-caca* Spix, 1825, near Poçoens Encima, Bahia.

Forms superspecies with *P. ochrogaster* and *P. pileata*, and all three once considered conspecific. Has hybridized with *P. pileata* in captivity. Monotypic.

Distribution. Interior of NE Brazil.

Descriptive notes. 65-70 cm. Conspicuous white supercilium with a narrow black line below, separating it from bare skin of sides of face. White streaks on upperwing elongated and prominent, more so than in *P. obscura bronzina*, from which present species also differs by having more contrasting supercilium and pale legs. Juvenile similar, with softer plumage; browner on breast.

Habitat. Inhabits dry areas of stunted forest and *caatinga*. In lowlands.

Food and Feeding. No information available on diet. Sometimes comes to ground to feed.

Breeding. No information available.

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. Currently considered near-threatened. Present at Raso da Catarina, NE Bahia, but considered scarce. Apparently still occurs in some densely populated areas and has been seen offered locally for sale. In 1988, was reckoned not to be rare overall, but under great pressure due to habitat loss and hunting. Uncommon in collections, but has been bred in Mexico and in Brazil.

Bibliography. Bronzini (1946), Collar & Andrew (1988), Eley (1979), Estudillo López (1983), Forrester (1993), Pinto (1964), Sick (1985a, 1993), Vaurie (1966b).

inches 12
30

Genus *PIPILE* Bonaparte, 1856

28. Trinidad Piping-guan

Pipile pipile

French: Pénélope siffleuse

German: Trinidadguan

Spanish: Pava de Trinidad

Taxonomy. *Crax pipile* Jacquin, 1784. Orinoco River near Cumaná; locality probably erroneous. All members of *Pipile* have been placed in genus *Aburria*, and previously even in *Penelope*. Present species forms superspecies with *P. cumanensis*, to which it is very closely related, and *P. cujubi*; all three often treated as conspecific; the more distinct *P. jacutinga* also sometimes included in the superspecies, or even in expanded species, making genus *Pipile* monospecific. Monotypic.

Distribution. Trinidad.

Descriptive notes. c. 69 cm. More brownish and less glossy than *P. cumanensis*, and with predominantly dark crest; gloss is purplish brown; breast has white markings faint or lacking.

Habitat. Remote primary forest in areas of minimal human disturbance; favours sites with sparse ground cover and closed canopy, rich in vines and epiphytes; lower montane rain forest in Northern Range and semi-evergreen seasonal forest in Southern Range; prefers steep hilly areas with deep valleys and abundant water courses, between 400 m and 900 m. Some records from second growth, coffee plantations and cultivated plots adjacent to primary forest.

Food and Feeding. Mainly fruits and seeds of trees including those of *Ocotea*, *Pouteria*, *Bursera*, *Didymopanax* and *Erythroxylum*; also of *Lantana* in second growth; young leaves and insects occasionally reported. Drinks from streams and forest epiphytes. Forages in small groups usually of up to 5 birds, although old records mention flocks of 12-15 birds; forages most often in the evening, extending 1-2 hours after dark (see page 323).

Breeding. Seems to have a protracted season; records of breeding activity in most months. Nest is stick platform usually located within tangle of vegetation. 2 eggs. No further information available.

Movements. Mainly sedentary, but in Northern Range birds move locally over large areas in search of fruit.

Status and Conservation. ENDANGERED. Situation serious; action urgent. CITES I. Formerly abundant and widely distributed, at least in N and S of island; relatively large numbers probably remained until 1940's or 1950's. Currently only two small, widely disjoint populations survive, one in the Northern Range and the other in the Southern Range. Total population roughly calculated to number c. 100 birds in 1980. Habitat loss and hunting pressure are causes of marked decline that species has undergone. Intensive timber extraction, conversion of forests into commercial timber plantations, and construction of access roads for agriculture (also bringing in settlers) continue to be main threats, along with tourism. Decline caused by hunting was already reported in 1894 and has continued until present day, despite legal protection of species since 1963; high levels of illegal hunting blamed for absence of species in accessible areas of Northern Range where ecological conditions seem to be ideal. Most of species' current range lies within reserves or state forests, but existing laws concerning hunting, settling and logging are not enforced. Conservation education campaigns about the species, the country's only endemic bird, were carried out throughout 1980's.

Bibliography. Belcher & Smoother (1934-1937), Collar *et al.* (1992), French (1969, 1973, 1992), Herklots (1961), James & Hislop (1988), Junge & Mees (1958), King (1978/79), Salvadori (1914), Vaurie (1967a).

29. Blue-throated Piping-guan

Pipile cumanensis

French: Pénélope à gorge bleue

German: Blaukehlguan

Spanish: Pava Goliazul

Other common names: Common Piping-guan; White-headed Piping-guan (*cumanensis*); Gray's Piping-guan (*grayi*)

Taxonomy. *Crax cumanensis* Jacquin, 1784. Orinoco River region near Cumaná.

All members of *Pipile* have been placed in genus *Aburria*, and previously even in *Penelope*. Present species forms superspecies with *P. pipile*, to which it is very closely related, and *P. cujubi*; all these forms often treated as conspecific, with *P. pipile* as species name; some authors also include the more distinct *P. jacutinga*. Race *grayi* has been considered a separate species, but intergrades with nominate in SE Peru. *P. cujubi nattereri* has been considered race of present species, but is sympatric with *P. cumanensis grayi* in S Mato Grosso. Present species has hybridized with *Ortalis canicollis* in captivity. Two subspecies recognized.

Subspecies and Distribution.

P. c. cumanensis (Jacquin, 1784) - the Guianas, Venezuela S of R Orinoco, NW Brazil and Amazonian parts of C & E Colombia, E Ecuador and E Peru.

P. c. grayi (Pelzelin, 1870) - SE Peru, Amazonian NC & E Bolivia, SW Brazil and NE Paraguay.

Descriptive notes. 60-69 cm; 1200-1350 g. Blacker and glossier than *P. pipile*; glossy greenish blue (*cumanensis*) or greenish with only a few bluish tints (*grayi*). Colour of dewlap and bare facial skin varies considerably between white and cobalt blue. Race *grayi* has long, slender caruncle hanging from throat; white patch on nape more developed, and white patch on wing large and uniform.

Habitat. Humid *terra firme* and *várzea* forest, semi-deciduous forest, gallery forest and *cerrado* woodland, mainly in tropical zone. In the Guianas reaches coastal lowlands, as well as broken country inland. Many populations in

Amazonia are closely tied to riverine strips of forest within 100 m of the river, also tied to margins

of large rivers in French Guiana, and similar preference also noted in Colombia and Venezuela. Nominative race occurs up to 500 m in Colombia and 1000 m in Venezuela; race *grayi* recorded in subtropical forest, at over 2000 m in Bolivia; perhaps only enters this habitat in search of fruiting trees. In Paraguay apparently prefers wooded slopes of conical hills.

Food and Feeding. Shows preference for palm fruits; also recorded feeding on flowers of a *Tubatitia* tree; figs and snails have also been found in stomachs. When not nesting, forages in flocks of up to 15 birds, mainly in canopy or sub-canopy, rarely on ground. Visits salt-licks.

Breeding. In Peru, starts in Aug-Sept, with chicks in Jan-Mar; in Colombia, eggs in Feb and May; breeds during rains in areas with seasonal rains. Nest built of twigs, and placed in dense canopy vegetation. 3 eggs; incubation c. 24 days.

Movements. Presumably mainly sedentary. Possibly makes some altitudinal movements in search of fruiting trees. In Mato Grosso, Brazil, makes local movements up or down river.

Status and Conservation. Not globally threatened. Nominative race considered not uncommon in Surinam in 1968; evidently rare and very local in French Guiana, where considered vulnerable; considered local in Colombia and in Amazonas, Venezuela. Still common in Ecuador in undisturbed forests, with estimated density of 21-6 birds/km² in its preferred river edge forest habitat. In Peru, fairly common to common in S, but uncommon to rare in NE, where there is some danger of local extinction; preference for river edges and conspicuous habits have apparently rendered present species more vulnerable than other cracids of tropical forests. In Brazil, fairly common in N Roraima; scarce around cities of Tefé and Manaus, Amazonas; not recorded in recent times from Amapá. Race *grayi* common in entire Pantanal region of S Mato Grosso. Hunted for local food consumption, and locally for commercial purposes; also suffers in places from habitat destruction, mainly for agriculture. Nominative race quite common in captivity, where frequently bred; race *grayi* also present, and bred, in a few collections.

Bibliography. Belterman & de Boer (1990), Duhs (1992), Forester (1993), Haverschmidt (1968), Hernández & Rodríguez (1988), Hilly & Brown (1986), Johnson (1993), Meyer de Schauensee & Phelps (1978), Ortiz, E. & O'Neill (1988), Ortiz, E. (1981), Pinto (1938, 1964), Porras & Arriaga (1981), Remsen & Traylor (1989), Salvadori (1914), Sick (1985a, 1993), Snyder (1966), Strahl & Silva (1988), Thibault & Guyot (1988), Tostain *et al.* (1992), Traylor (1958), Vaurie (1967a), Willard *et al.* (1991).

30. Red-throated Piping-guan

Pipile cujubi

French: Pénélope cujubi

German: Rotkehlguan

Spanish: Pava Cuyubi

Other common names: Stripe-crowned Piping-guan (*cujubi*); White-headed/Natterer's Piping-guan (*nattereri*)

Taxonomy. *Penelope cujubi* Pelzelin, 1858. Pará.

All members of *Pipile* have been placed in genus *Aburria*, and previously even in *Penelope*. Present species forms superspecies with *P. pipile* and *P. cumanensis*, and all three often treated as conspecific, with *P. pipile* as species name; some authors also include the more distinct *P. jacutinga*, of which present species was in past considered race. Race *nattereri* has been considered a distinct species, or race of *P. cumanensis*, but sympatric with race *grayi* of latter in S Mato Grosso. Has hybridized in captivity with *Penelope supercilialis*. Two subspecies recognized.

Subspecies and Distribution.

P. c. cujubi (Pelzelin, 1858) - NC Brazil S of R Amazon, from lower R. Madeira to N Pará.

P. c. nattereri Reichenbach, 1862 - S & W Amazonia in W Brazil, up to border with Bolivia.

Descriptive notes. 69-76 cm; 1100-1300 g (*nattereri*). Nominative race has smaller areas of white on wing and crest, and usually has shorter dewlap than *nattereri*; also glossier, bluer plumage.

Habitat. Tropical forests, including riverine forests, in lowlands.

Food and Feeding. No information available on diet. Known to forage in flocks of up to 30 or more birds.

Breeding. No information available.

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. Nominative race fairly common in Amazônia National Park, Amazonas, and in parts of Rondônia; not recorded since at least 1960 around Belém and Santarém, Pará. Race *nattereri* fairly common to uncommon in N Mato Grosso, and probably also throughout most of range. Species very rare in captivity, but both subspecies present in one collection in Mexico.

Bibliography. Duhs (1992), Forester (1993), Hilly & Brown (1986), Pinto (1938, 1964), Remsen & Traylor (1989), Salvadori (1914), Sick (1985a, 1993), Vaurie (1967a).

31. Black-fronted Piping-guan

Pipile jacutinga

French: Pénélope à front noir

German: Schwarzmaskenguan

Spanish: Pava Yacutinga

Other common names: White-crested Piping-guan

Taxonomy. *Penelope jacutinga* Spix, 1825, between Bahia and Rio de Janeiro.

All members of *Pipile* have been placed in genus *Aburria*, and in past even in *Penelope*. Present species is most distinctive *Pipile*; has been considered to form superspecies with other members of genus, or even to be conspecific with them. *P. cujubi* was formerly considered race of present species. Range of present species meets *P. cumanensis* in E Paraguay, with no evidence of interbreeding. Monotypic.

Distribution. SE Brazil (S Bahia to Rio Grande do Sul), NE Argentina (Misiones and adjacent NE Corrientes) and SE Paraguay. Has disappeared from most of former range, and now very localized. **Descriptive notes.** 63-5-74 cm; 1100-1400 g. Only member of genus with black forehead, and with bare facial skin restricted to broad eye-ring. Chin and upper throat fully feathered. Large white wing patch with characteristic pattern produced by black tips of upperside-coverts. Juvenile similar to adult.

Habitat. Atlantic forest formations, including gallery forest, in lowlands and coastal ranges, up to 1850 m. Particularly favours forests rich in palmito (*Euterpe edulis*). Field work in several areas.

especially in Misiones, Argentina, show that species is very much tied to strips of forest close to streams or rivers, and is much rarer in forest interior.

Food and Feeding. Mainly fruits, especially those of palmito (*Euterpe edulis*); also of wild figs (*Ficus*), araçazeiros (*Psidium*), bicuiba (*Virola*), pindaúba (*Xylopia*), guarumo (*Cecropia*), *Hymaenea* and *Myrcia*. Seeds, grains and buds also recorded, and occasionally insects and even molluscs, which are taken among stones at side of a stream. Probably takes salt from mud. Forages alone, in pairs or in small groups; mainly in trees, but occasionally comes

to ground to take fallen fruits of e.g. *Virola*, or to drink; often forages in higher parts of emergent trees.

Breeding. Chicks in Oct (Misiones), Nov (Rio Grande do Sul). Nests found were platforms of twigs and stems, located on forks of trees. 2-3 eggs, perhaps up to 4; incubation c. 28 days. No further information available.

Movements. Altitudinal movements of birds inhabiting coastal ranges are known from several localities, mainly related to the availability of palmito fruit, which ripens earlier at lower altitudes. At any rate in past, some areas visited seasonally, e.g. Arroio Grande, Rio Grande do Sul, where species arrived in May-Jun and left in Dec, after nesting. Also used to appear in fair numbers in Santa Catarina during cold winters.

Status and Conservation. VULNERABLE/RARE. Populations only partly protected. CITES I. Formerly common or even abundant, at least seasonally; c. 50,000 birds killed in few weeks during cold winter of 1866 along lower R Itajaí, Santa Catarina. Since that period, species has declined markedly throughout range, and has virtually disappeared from N part; in S portion, now restricted to a few particular areas; migratory habits make its conservation in small areas difficult. In Brazil, fragmented populations small or very small; one of best occurs in Carlos Botelho State Park, São Paulo, where isolated birds or groups of 2-8 individuals observed 117 times between Jan 1985 and Sept 1986; long assumed to have disappeared from interior of São Paulo State, but one individual seen in Serra do Japi in 1988, although could have been an escaped bird; in 1986 reported from Miranda, Mato Grosso, extending known range to NW. In Paraguay currently uncommon, but suitable habitat remains in Alto Paraná and Canendiyú. In Argentina generally very rare, though locally commoner, e.g. in Uruguá-i Provincial Park, Misiones; also occurs in Iguazú National Park (55,000 ha), Misiones, where strict control led to slight increase in numbers between 1980 and 1985. Main cause of decline is habitat loss, through deforestation, hydro-electric developments and exploitation of palms within forests; in Argentina, its main food, palmito, has been overexploited to extinction. Hunting pressure also very important, and species long persecuted for feathers and food, causing local extinction at many sites, e.g. Sooretama Reserve, Espírito Santo; poaching is currently major cause of decline in several protected areas. Captive breeding achieved in several places. An undocumented attempt to reintroduce species in Sooretama Reserve failed.

Genus *ABURRIA* Reichenbach, 1853

32. Wattled Guan

Aburria aburri

French: Pénélope aburri **German:** Lappenguan **Spanish:** Pava Aburria
Other common names: Wattled Piping-Guan

Taxonomy. *Penelope aburri* Lesson, 1828, temperate and cold lands in the mountains of New Grenada. Monotypic.

Distribution. W Venezuela and N Colombia S to SC Peru.

Descriptive notes. 72.5-77.5 cm; 1195-1550 g. Long, slender, bright yellow and red wattle hangs from throat, a feature unique to this species. Juvenile similar to adult, with less developed wattle.

Habitat. Wet mountain forest, borders of forest and tall second growth adjacent to primary forest. Mainly in subtropical zone, but also in hilly areas of upper tropical, pre-montane zone; sometimes, perhaps seasonally, ascends to lower limit of temperate zone. In Colombia occurs between 600 m and 2500 m, almost always in steep mountainous terrain; in Venezuela up to 1400 m; in Peru usually between

1000 m and 1900 m, with one record at 500 m and another at 2300 m. In Ecuador occurs only on the more humid E slope of the Andes and likewise in most of Peru, although has also been reported on W slope in Taulis, Cajamarca.

Food and Feeding. Fruit. Forages mainly between middle and upper storeys of fruiting trees, usually in pairs or groups of 3 birds.

Breeding. Sept-Mar in Peru; season considered to coincide with that of *Penelope barnata* in S Ecuador and N Peru, with chicks recorded Dec-Feb; in SW Colombia, most calling in Dec-Feb, and one adult with chicks in Mar. No further information available.

Movements. Presumably sedentary. Records of species in temperate zone have been attributed to possibly seasonal local movements.

Status and Conservation. Not globally threatened. Currently considered near-threatened. Threatened by loss of habitat over much of Colombian range, though considered numerous in 1986 in Cueva

de los Guácharos National Park, SW Colombia; status in Colombia classed as indeterminate in 1990. Local in Venezuelan part of range. In Peru, species may be seriously threatened, if not extinct, on W slope of Andes; on E slope is rare or has disappeared from around settlements, uncommon in large stretches of Hualallaga Valley due to habitat alteration for coca plantations, but still fairly common in other areas where forest is in good condition, e.g. in Jirillo, San Martín, and Coshipata, Cuzco. Its noisy habits and tendency to stay in branches when spotted make species particularly vulnerable to hunting; this, along with its relatively large size and good taste of its flesh, explains heavy persecution in many parts of range. Also suffers habitat destruction, as its altitudinal range coincides with an area where deforestation is especially frequent in the Andes. Taulis area in Peru should be urgently surveyed, to see if species survives on W slope of Andes in Peru; adequate protected areas should be established on both slopes in Peru, where species has not been recorded in any of existing protected areas. Very rare in captivity, but has been bred in one collection in Mexico.
Bibliography. Beebe (1947), Fjeldsá & Krabbe (1990), Hernández & Rodríguez (1988), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Ortiz, E. & O'Neill (1988), Ortiz, F. (1981), Ortiz, F. & Carrión (1991), Parker *et al.* (1982), Porras & Arriaga (1981), Strahl & Silva (1988), Traylor (1958), Vaurie (1967b).

Genus *CHAMAEPETES* Wagler, 1832

33. Black Guan

Chamaepetes unicolor

French: Pénélope unicolore **German:** Mohrenguan **Spanish:** Pava Negra
Other common names: Black Sickie-winged Guan

Taxonomy. *Chamaepetes unicolor* Salvin, 1867, Veragua.

Forms superspecies with *C. goudotii*. Monotypic.

Distribution. Mountains of Costa Rica and Panama.

Descriptive notes. 62-69 cm; c. 1135 g. Uniform black plumage; bare blue facial skin; red eyes. Juvenile similar to adult, but less glossy and with slightly browner underparts.

Habitat. Mountain cloud forest. Prefers steep terrain with ridges and ravines, but occasionally enters more open areas. Occurs in upper tropical, subtropical and temperate zones, up to 2500 m, near tree-line, in Panama; usually not below 1000 m, although one record at 450 m in Bocas del Toro, Panama.

Food and Feeding. Mainly fruits, including a wide range of types and sizes; in one study at Monteverde Cloud Forest Reserve, Costa Rica,

fruits of 26 species of plants were consumed, 11 of them commonly (*Beilschmiedia*, *Ocotea*, *Urera*, *Ardisia*, *Ilex*, *Guarea*, *Citharexylum*, *Guetarda*, *Chamaedorea*); in the same study, leaves of two species of *Asteraceae* were also taken, mainly during afternoon, while fruits were consumed at any time of day. Birds also seen taking fruits of guarumo trees (*Cecropia*). Seeds are defecated intact, and, as, unlike other smaller frugivores, present species rarely deposit seeds under parent plant, it seems to play an important dispersing role. Forages singly, in pairs or in small groups, mostly in trees; at times comes to ground, mainly to take fallen fruit.

Breeding. In Panama, young seen in Feb and Jun; pairing begins in Mar in Costa Rica, with very small chicks and almost full grown young being recorded at the same locality two days apart in Jul; this might suggest that replacement clutches can be laid. Lays 2-3 eggs; chicks have brown down, with a striped pattern on the head. No further information available.

Movements. Presumably sedentary, but no specific information available.

Status and Conservation. Not globally threatened. Currently considered near-threatened. In Costa Rica fairly common in several remote or protected areas, especially at Monteverde Cloud Forest Reserve, where a density of 4 pairs/km² was estimated at beginning of 1990's; scarce and wary where hunted. Reported as common in several areas of Panama during 1930's, but regarded as uncommon and very local in 1971; at that time extinction from Panama was already feared for near future if effective protective measures were not taken; in 1989 generally considered rare, but locally still moderately numerous. Much hunted for food. Very rare in captivity, but has been bred in one collection in Mexico.

Bibliography. Ridgely & Gwynne (1989), Ridgway & Friedmann (1946), Slud (1964), Stiles & Skutch (1989), Vaurie (1967b), Wenny (1993), Wetmore (1965), Wheelwright *et al.* (1984).

34. Sickie-winged Guan

Chamaepetes goudotii

French: Pénélope de Goudot **German:** Sichelguan **Spanish:** Pava Falcilar
Other common names: Goudot's/Rufous Sickie-winged Guan

Taxonomy. *Ortalia Goudotii* Lesson, 1828. Quindíu = Quindío region, Central Andes, Colombia. Forms superspecies with *C. unicolor*. Five subspecies recognized.

Subspecies and Distribution.

- C. g. goudotii* (Lesson, 1828) - Andes of C & W Colombia.
- C. g. sanctaemariae* Chapman, 1912 - Santa Marta Mts, N Colombia.
- C. g. jagani* Chubb, 1917 - W slope of Andes in SW Colombia and Ecuador.
- C. g. tsehudii* Taczanowski, 1886 - E slope of Andes in S Colombia, Ecuador and N Peru.
- C. g. rufiventris* (Tschudi, 1843) - E slope of Andes in C Peru.

In 1981 a new population was discovered in Departamento La Paz, Bolivia, and was said to represent a new, undescribed race; this was also interpreted as an indication that species has continuous distribution in appropriate habitat types from Colombia to C Bolivia, being easily overlooked due to its secretive habits, this possibly accounting for the apparent large gap in S portion of range.

Descriptive notes. 50-65 cm (races *tsehudii* and *rufiventris* largest); 550-800 g. Unmistakable combination of bright chestnut belly, pale blue facial skin and red eyes. Juvenile similar to adult, but duller. Races vary in size and tone of plumage coloration; race *rufiventris* has grey margins on neck feathers, producing scaly appearance.

Habitat. Humid and wet forests and forest borders of subtropical and, to lesser extent, lower temperate zones, on both slopes of Andes. In Colombia, mainly between 1100 m and 2500 m, but locally as high as 3000 m, e.g. in Santa Marta Mts, or as low as 500 m on Pacific slope. In Peru usually occurs

between 1500 m and 2500 m, but there are records at 900 m in Amazonas and at 3000 m in Puno. Newly discovered Bolivian population found at unusually high altitude of 3300 m. Mutual exclusion has been reported between present species and *Penelope montagnii*, with latter usually displaced to higher altitudes; but opposite occurs in Bolivia, at S extreme of range. Generally on steep hills with difficult access, mainly in zones of very high precipitation; prefers tall forest, but occasionally also recorded in second growth and lighter open woodland, like coffee plantations, at lower altitudes.

Food and Feeding. Mainly fruits, in 1-10 mm range; also seeds and leaves of several kinds. Despite repeated statements about mainly terrestrial habits, and occasional records of birds taking food from the ground, it seems that present species feeds mainly in fruiting trees, usually in middle storey or higher, in pairs or small groups of 3-5 birds, typically around dawn and dusk.

Breeding. Chicks recorded in Jun (Colombia), Sept (N Ecuador) and Feb-May (Peru). Chicks are chocolate brown above, with sooty black cap and throat, paler below.

Movements. Mainly sedentary. Performs some seasonal altitudinal movements, at least in parts of range. Records of birds descending to coffee plantations and second growth are always outside breeding season.

Status and Conservation. Not globally threatened. Currently suspected to be locally fairly common, and in Colombia is one of the few guans that can still be seen near or alongside roads in several areas; status in Colombia indeterminate in 1990. In Peru still common in some areas, although threatened locally; in the Huallaga Valley, threatened by forest destruction for coca plantations. Race *sanctaeamarthae* considered abundant in parts of the Santa Marta Mts in 1923; has declined and in 1990 classed as Indeterminate, probably at least vulnerable, by ICBP/IUCN International Cracidae Specialist Group. Habitat frequently altered in lower part of its altitudinal range; more secure at higher altitudes, due to inaccessibility. In contrast with other cracids, like *Aburria* and *Mitu*, quickly hides under cover when disturbed; this, together with its smaller size and rugged habitat, renders species less vulnerable to hunting; nevertheless, numbers have been much reduced around villages. Very rare in captivity, but has been bred in one collection in Mexico.

Genus *OREOPHYSIS* G. R. Gray, 1844

36. Horned Guan

Oreophasis derbianus

French: Oréophas cornu

German: Zapfenguan

Spanish: Pavón Cornudo

Other common names: Derby's Guan, Lord Derby's Mountain Pheasant

Taxonomy. *Oreophasis Derbianus* G. R. Gray, 1844, Guatemala.

This very distinct species has been considered intermediate between the guans and the curassows, sometimes separated in a tribe, or even subfamily, of its own (see page 311). Monotypic.

Distribution. SE Mexico (S Oaxaca and Chiapas) and Guatemala; there is also a probable record from Honduras, which remains unconfirmed.

Descriptive notes. 75-85 cm. Unmistakable. Sexes alike; formerly alleged differences now attributed to different ages of birds. Juvenile similar, but duller and with truncated horn.

Habitat. Humid evergreen mountain forest in subtropical zone, chiefly from 2300 m to 3100 m, occasionally as low as 1525 m, and very locally, in optimum habitat, up to 3350 m. Generally in areas with luxuriant undergrowth, with abundance of ground- and tree-ferns, epiphytes, mosses and creepers. Although the broad-leaved forest that species inhabits can be mixed with cypress or pine to some extent, species avoids drier slopes dominated by oak-

pine forest.

Food and Feeding. Mainly fruits and green leaves; studies at El Triunfo, Chiapas, have recorded the fruits of 37 plant species from 18 families (notably Lauraceae, Araliaceae and Liliaceae), the leaves of five others (*Anthurium*, *Eupatorium chiapense*, *Schistocarpus bicolor*, *Cobaea scandens* and an untraced species of Scrophulariaceae, known as "cola de caballo"); also both fruits and leaves of *Solanum*. Buds and shoots have also been mentioned by other authors, as have invertebrates, mainly Orthoptera and their larvae, although in the most recent studies species is described as strictly vegetarian, with even young being fed on regurgitated fruit and fragments of green leaves. Has been seen walking and scratching vigorously, although the claim that it feeds primarily on the ground is clearly unlikely. Sometimes drinks water trapped in bromeliads.

Breeding. In El Triunfo mainly in low rainfall months of Feb-Mar, so that when rains return, by May, young are already half-grown; in Volcán Tacaná, season starts in Jan or before. Probably polygynous; male may have access to 3-5 females during breeding season. Nest located very high in trees (one was at 16.5 m, another at 22 m), usually in vicinity of running water; there are some dubious records of nests placed on the ground; nest is a rudimentary structure made of dry leaves and roots of epiphytic and parasitic plants. Lays 2 eggs; incubation 34-36 days; chicks have a combination of pale and dark brownish grey down above, with a chestnut stripe on the head, and paler underparts. Sexual maturity appears to be reached at 4 years in males (in captivity), and perhaps at 1 year in females; the age of an incubating female in a nest found in the wild was estimated, by size and horn length, at 12-14 months.

Movements. No information available, but presumably sedentary.

Status and Conservation. VULNERABLE/RARE. Populations only partly protected. CITES I. Clearly reduced in numbers during the 20th century; a marked decline was already recognized in Guatemala during 1930's, with birds not found for many years at localities where they had formerly been common. Also known to have declined seriously in Mexico by 1960's. At end of 1970's, total population estimated at under 1000 birds. In contrast, species found in the mountains of S Oaxaca in 1989 and has also recently been discovered in Sierra de las Minas, E Guatemala, where still considered to be common according to local report; there are other areas within its range, especially with impassable terrain, where it probably still occurs; local inhabitants have reported "large birds with single red horns" at Cerro Volcán Pacayita Biological Reserve, Honduras. Extensive deforestation, mainly for farming and establishment of coffee plantations, and extending above 2000 m in some places, has been one of the main reasons for decline suffered in both Mexico and Guatemala; in W Guatemala this has halved the area of potential habitat for the species, formerly estimated at 6000 km²; marble mining is serious threat to populations in E Guatemala, as implies complete clearance of cloud forest. Hunting, mostly for food by coffee plantation workers, is also a severe threat, as species is very vulnerable due to its great size and tameness; this factor has already been blamed for local extinction of species in some areas. The species is also persecuted for illegal trade, as demonstrated by the presence of 20 individuals offered for sale in a market in Tapachula, Chiapas, in 1991; all were juveniles of c. 1 year old, probably captured on Volcán Tacaná. Locally, livestock grazing in forest undergrowth and military operations have also contributed to decline. The species is protected in Mexico and Guatemala, but hunting laws are not enforced in either country. Several reserves in Mexico and national parks in Guatemala hold the species; most important are El Triunfo Biosphere Reserve, Chiapas, in Mexico, and Lago de Atitlán National Park in Guatemala; in Guatemala, species may also occur in three private reserves. The creation of several additional protected areas is badly needed; the unprotected Volcán Tacaná, on the border between Mexico and Guatemala, which holds one of largest remaining populations, could be established as an international park. Kept in captivity in Tuxtla Gutiérrez Zoo, Chiapas, and in private collection of J. Estudillo, Mexico, where at least 15 birds had been raised successfully by 1992.

Bibliography. Alvarez del Toro (1976, 1981a, 1981b), Andrie (1967a, 1969a, 1969b), Anon. (1989b, 1991b), Baepler (1962), Binford (1989), Collar & Andrew (1988), Collar *et al.* (1992), Estudillo López (1979b, 1983, 1986), González-García (1984, 1988a, 1988b, 1988c, 1991, 1993a, 1993b, 1994), González-García & Bubb (1989), Griscom (1932), Howell & Webb (1992a), King (1978/79), LaBastille (1973), Land (1970), Leopold (1959), Ortega & Aragón (1981), Parker *et al.* (1976), Ramos (1985), Ridgely & Friedmann (1946), Salvin (1860), Saunders (1950), Vannini & Rockstroh (1988), Veblen (1976), Wagner (1953), Wall (1992), Wetmore (1941), Zepeda (1981).

Genus *PENELOPINA* Reichenbach, 1862

35. Highland Guan

Penelopina nigra

French: Pénélope pajuil

German: Schluchtenguan

Spanish: Pava Pajuil

Other common names: Black Chachalaca, Black Pajuil, Black Guan (!), Little Guan, Penelopina

Taxonomy. *Penelope niger* Fraser, 1850, Locality unknown, described from aviary specimens.

A very distinctive species, probably most closely related to *Chamaepetes* (see page 314). Two subspecies (*dickeyi*, *rufescens*) have been described on the basis of variation in the colour of the bare facial skin, but validity doubtful. Monotypic.

Distribution. S Mexico (Oaxaca and Chiapas) S to N Nicaragua.

Descriptive notes. 59-65 cm; 866-914 g. Marked sexual dimorphism, with female larger than male, profusely barred and lacking dewlap. Juvenile similar to adult female, but less distinctly patterned.

Habitat. Wet pre-montane and montane broad-leaved forests of subtropical and temperate zones, from 900 m to c. 3300 m. Prefers the most humid, most heavily forested, steepest slopes and ravines, but occasionally also present in drier pine-oak forests. Does not appear to utilize plantations, even where original canopy has been left for shade.

Food and Feeding. Berries and other fruits make up much of diet; some animal items have often been recorded, including a small mouse and a salamander. Forages singly, in pairs or in small groups of 3-4 birds, often in twilight. Comes down to feed on ground on occasion.

Breeding. Mar-May; chicks observed in Apr both in Guatemala and Oaxaca, Mexico. In a study in Guatemala, sex ratio apparently biased towards females, and polygyny is suspected. Nest is a fairly large, loose structure made of sticks and other plant material, lined with leaves and some of female's feathers, usually situated in trees 2.5-13 m high, occasionally nests in a depression on the ground. 2 eggs; chicks have black down mixed with buffy and brown.

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. Currently considered near-threatened. Population has certainly been reduced as highland habitats of Central America have been altered. Encountered in moderate numbers in El Triunfo Biosphere Reserve, Chiapas; considered uncommon and local in Chimalapa region, Oaxaca, Mexico. Still locally common in areas of Guatemala, such as upper altitudes of Volcán Santa María, Volcán de Fuego, Volcán de Agua and the Atilán complex; readily observed at Biotopo Mario Dary, in Baja Verapaz. Considered uncommon and rather local in Honduras and N Nicaragua. In optimal regions it has recently been found that species can reach densities of 30 or more birds/km². Species may have been extirpated from El Salvador. Considered most endangered cracid in Nicaragua, due to extensive loss of its natural habitat. Apparent dependence on undisturbed, pristine forests renders it particularly vulnerable to habitat alteration. Locally threatened in Guatemala by marble quarrying operations, involving clearance of forests covering the mountain ridges, particularly in the Sierra de las Minas and the Sierra del Merendón. Very rare in captivity, but has been bred in one collection in Mexico. CITES III in Guatemala.

PLATE 33

inches 16
cm 40

barred morph

44

Subfamily CRACINAE

Genus *NOTHOCRAX* Burmeister, 1856

37. Nocturnal Curassow

Nothocrax urumutum

French: Hocco nocturne German: Rothokko Spanish: Paují Nocturno
Other common names: Rufous/Flat-crested/Urumutum Curassow, Urumutum

Taxonomy. *Crax urumutum* Spix, 1825, Rio Negro, Brazil. Formerly included, together with all other curassows, in *Crax*, but certainly distinct (see page 314). Most closely related to *Mitu*. Monotypic.
Distribution. Upper and middle Amazonia in S Venezuela, SE Colombia, E Ecuador, NE Peru and W & C Brazil.

Descriptive notes. 50-57.5 cm; one bird 1250 g. Unmistakable. Differs from all other curassows by smaller size and cryptic plumage in both sexes. Female similar to male, but has sides more heavily vermiculated. Juvenile very similar to adult.

Habitat. Dense humid forest, in *terra firme* forest and also permanently or seasonally flooded forests, usually near rivers. Apparently favours low-lying, partially flooded areas. Reported to occur in mature forest with flat or slightly undulating relief, generally below 800 m.

Food and Feeding. Forages, at least partially, during day-time, probably mainly around dawn and dusk. Forages singly, in pairs or in small parties; groups of 3-4 birds seen on ground under fruiting trees at dusk.

Breeding. Heard Oct and Jan-Feb and one female laying in Oct, in upper Rio Negro, Colombia. Monogamous, at any rate in captivity. Nest seems to be a rather large, loosely worked structure made of sticks, and placed in tree (one in a vine-covered tree, 4 m above ground), or on stumps or logs, not far above ground level. Lays 2 eggs; incubation 28-29 days (in captivity); chicks blackish brown above, buffy brown and white below. One female of unknown age died after being kept 16 years at Houston Zoo, Texas (USA).

Movements. No information available; presumably sedentary.
Status and Conservation. Not globally threatened. Status poorly known, but species probably reasonably secure, as parts of large range in W Amazonia are still in good condition. In Colombia reported to be numerous in Rio Guainía region and on Rio Vaupés at Caño Ti, W of Mitú, and thought possibly to be commoner in blackwater region of R Orinoco and R Negro than in S Amazonia. Considered common in Loreto, Peru, even at a distance of only 2 km from densely populated areas, e.g. along R Napo; population density estimated at 4-6 birds/km². Reported to be uncommon in Amazonas, Peru, apparently due to habitat destruction and conversion for agriculture. In Brazil, considered scarce in Rondônia; not recorded since at least 1960 from Pico da Neblina National Park, Amazonas. Its secretive habits may render species less vulnerable to hunting pressure; in some areas its call is frequently reported, where populations of other curassows have been severely devastated by hunters. Uncommon in collections but has been bred in a few, e.g. in USA (Texas), Mexico and Belgium.

Bibliography. Amadon (1979), Berry (1981), Estudillo López (1977), Hernández & Rodríguez (1988), Heyland (1970), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Ocampo (1981), Ortiz, E. & O'Neill (1988), Ortiz, F. (1981), Ortiz, F. & Carrión (1991), Parker *et al.* (1982), Pinto (1964), Porras & Arriaga (1981), Ruschi (1979), Sick (1970, 1985a, 1993), Strahl & Silva (1988), Tahel (1969b), Todd *et al.* (1992).

Genus *MITU* Lesson, 1831

38. Crestless Curassow

Mitu tomentosa

French: Hocco de Spix German: Samthokko Spanish: Paují Culicastaño
Other common names: Lesser Razor-billed Curassow

Taxonomy. *Crax tomentosa* Spix, 1825, "in Sylvius paludosis fl. Nigri prope pagum Barcellonam." All members of genus form superspecies; all have been placed, together with the members of *Pauxi*, and less often *Nothocrax*, in *Crax*. Range meets that of *M. salvini* in C Colombia, without any evidence of interbreeding. Monotypic.

Distribution. Guyana, Venezuela S of R Orinoco, NW Brazil and E Colombia.
Descriptive notes. 75-85 cm; male 2600-3050 g, female 2000-2450 g. Lacks crest and also any swelling on red bill. Combination of rich chestnut belly and tail tips characteristic.

Habitat. Rain forest, mainly along rivers; in Colombia, humid *terra firme* forest, especially along small streams. Also in gallery forest, e.g. in S llanos of Colombia and Venezuela. Partial to areas with thick undergrowth. In lowlands, up to 500 m in Colombia, to 600 m in Venezuela.

Food and Feeding. No information on diet. Forages singly or in pairs, mostly on ground, although said to spend more time in trees than other curassows.

Breeding. Probably begins with arrival of rains; 2 nests with eggs in Jun in Orinoco, Venezuela. Nest placed low in trees. Lays 2 eggs; chicks have blackish down above, dotted with buffy brown and pale grey, underparts much paler. Birds have survived more than 10 years in captivity.

ter (1985), Hernández & Rodríguez (1988), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Pinto (1935, 1964), Porras & Arriaga (1981), Scheuerman (1977), Schiffer (1989), Sick (1985a, 1993), Snyder (1966), Strahl & Silva (1988), Vaurie (1967d), Willard *et al.* (1991).

39. Salvin's Curassow

Mitu salvini

French: Hocco de Salvin German: Salvinhokko Spanish: Paují Culiblanco
Other common names: Salvin's Razor-billed Curassow

Taxonomy. *Mitua salvini* Reinhardt, 1879, no locality = eastern Ecuador. All members of genus form superspecies; all have been placed, together with the members of *Pauxi*, and less often *Nothocrax*, in *Crax*. Range meets that of *M. tomentosa* in C Colombia, without any evidence of interbreeding. Also reported to be marginally sympatric with *M. tuberosa* at some localities in Peru. Monotypic.

Distribution. SC Colombia, E Ecuador and NE Peru.

Descriptive notes. 75-89 cm. Bill deep and laterally compressed, but not massive. Well developed crest usually carried depressed. Only *Mitu* with white abdomen.

Habitat. Humid *terra firme* forest; apparently avoids flooded areas. Usually in primary forest with flat or slightly undulating relief; occurs in lowlands, up to 600 m in Colombia.

Food and Feeding. Mainly fallen fruits and seeds, but apparently has rather broad diet; leaves also taken; also seen scavenging animal remains, in Macarena Mts, Colombia. Forages singly, in pairs or small family groups, mainly on ground.

Breeding. In a study in the Macarena Mts birds seen to associate in pairs all year round, and appear to have overlapping home ranges with loose territoriality. Lays 2 eggs; chicks brownish above, much paler below. No further information available.

Movements. No information available; presumably sedentary.

Status and Conservation. Not globally threatened. Few records from Colombia, although apparently occurs regularly in areas well away from human settlements; fairly common in Macarena National Park. In Amazonian Ecuador, present throughout the region, but in low numbers: a density of 3.8 birds/km² has been estimated in *terra firme* forest with low hunting pressure, whereas in forest with moderate hunting levels a density of only 1.6 birds/km² was calculated. In Peru, has declined around settlements, and reported to be rare near Iquitos, but fairly common in other areas; disappeared from around a densely populated area along R Napo, but survives, with healthy densities, 10-20 km back from the river. Actively hunted for local food consumption, and recorded for sale at market in Iquitos. Habitat destruction significant only locally. Uncommon in captivity, but has been bred in a few collections.

Bibliography. Haffer (1985), Hernández & Rodríguez (1988), Hilty & Brown (1986), Johnson (1993), Olsson (1971), Ortiz, E. & O'Neill (1988), Ortiz, F. (1981), Ortiz, F. & Carrión (1991), Parker *et al.* (1982), Scheuerman (1977), Vaurie (1967d).

40. Razor-billed Curassow

Mitu tuberosa

French: Hocco tuberculé German: Amazonashokko Spanish: Paují Tuberoso
Other common names: Greater/Amazonian Razor-billed Curassow

Taxonomy. *Mitu tuberosa* Spix, 1825, Rio Solimões, Brazil. All members of genus form superspecies; all have been placed, together with the members of *Pauxi*, and less often *Nothocrax*, in *Crax*. Often considered conspecific with *M. mitu* (see page 315). Has hybridized in captivity with several other species of curassow, including *Crax alberti*; at least some of these hybrids were fertile. Reported to be marginally sympatric with *M. salvini* at some localities in Peru. Monotypic.

Distribution. Amazonia, S of R Amazon, in extreme SE Colombia, Brazil, Peru and Bolivia.

Descriptive notes. 83-89 cm; up to 3860 g. Well developed crest usually carried depressed. Massive, casque-like bill. Juvenile similar to adult, but less glossy, with less highly developed crest.

Habitat. Forest, including humid *terra firme* forest, gallery forest, swampy areas in forests, smaller canopied forest streams and, at any rate in SE Peru, *várzea* forest. Usually in lowlands; occurs up to 300 m in Colombia, but recorded at 1340 m in Cordillera Vilcabamba, Peru.

Food and Feeding. Mainly fruits; also seeds and leaves; occasionally insects and other animals, including one caecilian (Gymnophiona) and frogspawn laid in small ponds. In one study in Cocha Cahu Biological Station, Manu National Park (Peru), 68 plant species were recorded as having been consumed; of fruits, those of *Pseudomedia*, *Clarisia racemosa* and *Leitonetea amazonica* were the most frequently taken; of leaves, several species of ferns (e.g. *Teactaria*, *Thelypteris*) were significant. Species forages singly, in pairs, or less often in groups of 3-5 birds, mainly on the

zônia (Tapajós) National Park, Pará; not recorded since at least 1960 from around the cities of Belém and Santarém, Pará. In Peru, reported to be common in areas with good forest, but rare or even extirpated near villages and major rivers; has disappeared from vicinity of a densely populated area on R Napo, but relatively common only 5-10 km from it; in Madre de Dios, reported to be present in disturbed areas if not hunted, even around populated zones, as long as there are dense thickets in which to hide; density of 16 individuals/km² estimated around Cocha Cashu Biological Station, Manu National Park. Particularly vulnerable to hunting, as tends to flee very noisily when alarmed, and to stop conspicuously on branches that lack any sort of cover. This, together with large size and much prized flesh, accounts for heavy persecution of species. Threatened locally by habitat destruction, e.g. in Huallaga Valley, NE Peru, for coca plantations. Quite common in captivity, where frequently bred.

Bibliography. de Boer & Belterman (1981), Dubs (1992), Forrester (1993), Haffer (1985), Heinroth (1931), Hernández & Rodríguez (1988), Hilty & Brown (1986), Koepcke & Koepcke (1963), Madariaga & Yarena de Vega (1981), O'Neill (1974), Ortiz & O'Neill (1988), Parker *et al.* (1982), Pinto (1935, 1964), Remsen & Traylor (1989), Rutgers & Norris (1970), Scheuerman (1977), Schifter (1989), Sick (1985a, 1993), Taibell (1969a), Terborgh (1986), Terborgh & Weske (1975), Todd *et al.* (1992), Torres (1989), Traylor (1958), Vaurie (1967d).

41. Alagoas Curassow

Mitu mitu

French: Hocco mitou

German: Mituhokko

Spanish: Paují de Alagoas

Taxonomy. *Crax Mitu* Linnaeus, 1766, Brazil and Guiana = north-eastern Brazil.

Mentioned by Marcgraf in 1648, its true existence was questioned for a long time until its rediscovery in 1951. All members of genus form superspecies; all have been placed, together with the members of *Pauxi*, and less often *Nothocrax*, in *Crax*. Often considered conspecific with *M. tuberosa* (see page 315). Monotypic.

Distribution. NE Brazilian coast, in recent decades only in Alagoas; formerly also in E Pernambuco; report of occurrence in N Bahia seems to be unreliable. Probably now extinct, or virtually so, in the wild.

1978 were feeding on fruits of *Eugenia*.

Breeding. One occupied nest found in Nov 1978 was situated in a tree, amidst thick foliage. Lays 2-3 eggs in captivity; downy chicks have upperparts rich orangish brown spotted with black, whitish throat and belly, and orangish brown breast. A captive-bred female laid her first clutch when 2 years old.

Movements. No information available, but presumably sedentary.

Status and Conservation. ENDANGERED. Situation critical: action urgent. CITES I. Discovered in early 17th century, then there was no further definite information about its existence until its rediscovery in 1951, at São Miguel dos Campos, Alagoas, where an adult female was collected. At that time, although species was fairly easily located, a rapid recent decline was evident. Assessments concluding species had probably become extinct were repeatedly made from about 1960 on, although fieldwork in the region showed that it was still extant, though with numbers extremely reduced, in 1960's and 1970's; the last known records correspond to an old bird killed by hunters in 1984, and another bird observed in 1987 and killed shortly afterwards. About 20 birds were estimated to survive in São Miguel dos Campos forests during 1960's; total population reckoned at less than 60 birds in 1986, but almost certainly far fewer birds survived, even if the captive population were included. Destruction of habitat has been main cause of disastrous decline; despite early warnings forecasting extinction of species, no effective action was taken to save it; cutting of forest proceeded, mainly for conversion to sugar cane plantations, and it was intensified during late 1970's in connection with a government programme to increase the production of fuel alcohol. Hunting pressure was also heavy, right from the time of the species' rediscovery, when a single hunter was reported to have killed many birds; this pressure demonstrated by last known records in the wild. Pesticides used in cane fields around the last forest patches may also have had detrimental effects. Attempts in 1983-1985 to capture birds for an official captive breeding programme failed, but breeding has been achieved regularly in the only captive population of the species, held since 1977 in the private collection of P. M. Nardelli in Nilópolis, Rio de Janeiro, and numbering 34 birds in 1993. This population, if suitably managed, holds the only chance of survival of the species, although reintroduction in the wild will be difficult, as virtually no adequate sites exist; only c. 800 ha of lowland forest remain in Alagoas, with an estimated capacity of some 32 pairs; protection and management of this area at São Miguel dos Campos, where a few individuals of the species may still persist, is in any case important for several other Neotropical endemics. See page 340.

Bibliography. Coimbra-Filho (1970, 1971), Collar & Andrew (1988), Collar *et al.* (1992), Estudillo López (1983), Haffer (1985), King (1978/79), Nardelli (1981, 1988, 1993), Pinto (1935, 1946, 1952b, 1954, 1964), Sick (1969, 1972, 1978, 1980, 1983, 1985a, 1993), Sick & Teixeira (1979), Teixeira (1986), Teixeira & Antas (1981), Vaurie (1967d).

ground; study in Cocha Cashu revealed that 95% of food was taken from ground, rest from trees and bushes at various different heights. Feeds near monkeys (*Cebus*, *Saimiri*), taking fruits that have fallen to the ground, before they decompose. Visits salt-licks.

Breeding. Nest placed in trees. Lays 2-3 eggs; incubation 30-32 days; chicks brownish above, whitish buff below. One male lived more than 23 years in captivity.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. Considered fairly common in many parts of Brazilian range, including Ama-

Genus *PAUXI* Temminck, 1813

42. Northern Helmeted Curassow

Pauxi pauxi

French: Hocco à pierre

German: Helmhooko

Spanish: Paují de Yelmo

Other common names: Helmeted/Galateated Curassow

Taxonomy. *Crax pauxi* Linnaeus, 1766, Mexico, error = Venezuela.

Both members of genus have been placed, together with those of *Mitu*, and less often *Nothocrax*, in *Crax*. Forms superspecies with *P. unicornis*, which has been considered a race of present species (see page 315). Race *gilliardi* has sometimes been considered specifically distinct, but differences very slight. Two subspecies recognized.

Subspecies and Distribution.

P. p. pauxi (Linnaeus, 1766) - NC & W Venezuela through Andes of Mérida across border into northernmost E Andes of Colombia.

P. p. gilliardi Wetmore & Phelps, 1943 - Sierra de Perijá, occurring on both sides of Venezuelan-Colombian border.

Descriptive notes. 85-92 cm; male 3500-3750 g; one female 2650 g. Large, fig-shaped (nominate race) bluish grey casque on forehead. Normal morph female like male; barred (rufous) morph is uncommon. Juvenile similar to adult, but shows some brown vermiculations on underparts and has smaller casque. Races vary in shape of casque, which is smaller and less swollen in *gilliardi*.

Habitat. Dense, wet, cool montane forest (cloud forest) on steep slopes in subtropical zone; also ranges into adjacent parts of tropical and temperate zones. Prefers very dense cloud forest, mainly between 1000 m and

1500 m, but has been recorded from 500 m up to 2200 m. In the Venezuelan Coastal Range, seems to prefer windward, N slopes. Particularly favours humid gorges with thick undergrowth of dwarf palms and terrestrial aroids, although females tend to select somewhat drier places when nesting. Avoids forest borders.

Food and Feeding. Mainly fallen fruits and seeds, which are taken from ground; also tender leaves, grasses and buds of undergrowth plants. Seeds of fruits are regurgitated. Forages singly, in pairs, or in family parties, occasionally in groups of up to 6 birds or more, only during first hours of the day and late afternoon.

Breeding. Territorial singing begins with the onset of the rainy season, usually in Dec; nests built in Mar-Apr; one juvenile of race *gilliardi* in Aug. Nest is a simple structure made of branches, twigs and leaves, lined with a few leaves, placed in forks or horizontal branches of a tree 4-6 m above the ground. Lays 2 eggs; incubation c. 34 days (one record of 30 days in captivity). No further information available.

Movements. Mainly sedentary, but it has been suggested that species makes some altitudinal movements, possibly in search of food.

Status and Conservation. ENDANGERED. Situation serious: action urgent. Common during last century in mountains of N Venezuela: in 1875 a collector took more than 50 specimens in just a few weeks. Still fairly common during 1950's, although by this time was already extirpated from settled areas and scarce at Henri Pittier National Park, N Venezuela, which held an estimated population of only 25-50 birds. In 1987 species was said to suffer a drastic decline in N Venezuela, although it seems to occur at a naturally low level of abundance (5-10 birds/km²); current status in Andes of Mérida is unknown. In Colombia, nominate race was considered very rare in 1965, and there appears to be no subsequent information. No information on status of race *gilliardi* in either Colombia or Venezuela, but it is also believed to be under considerable pressure; however, its range might extend further S than is currently known. Causes of the severe decline of the species in N Venezuela have been deforestation and indiscriminate hunting (for food and, in the case of Indians, also for its casque, or "helmet", that is used in necklaces), factors that also occur in other parts of species' range. Occurs in two national parks in Colombia (El Cocuy and Tamá) and three in Venezuela (Guatopo, Yacambú and Henri Pittier), but at any rate in Venezuela it is still hunted and suffering human disturbance associated with roads; the establishment of an international national park in Sierra de Perijá has been suggested as an essential measure for the protection of race *gilliardi*. A major education campaign concerning the conservation of the species is being mounted for both Colombia and Venezuela and is already being implemented in parts of Venezuela. Uncommon in captivity, but has been bred in a few collections, including one in Mexico where both subspecies are reared. CITES III in Colombia.

Bibliography. Collar & Andrew (1988), Collar *et al.* (1992), Estudillo López (1983, 1986), Ginés & Avelado (1958), Glover (1977), Hernández & Rodríguez (1988), Hilty & Brown (1986), Madariaga & Yarena de Vega (1981), Meyer de Schauensee & Phelps (1978), Negret (1987), Nicéforo María (1955), Nicéforo María & Olivares (1965), Ocampo (1981), Phelps & Phelps (1962), Porras & Arriaga (1981), Schäfer (1953a, 1954a), Schäfer & Phelps (1954), Strahl & Silva (1987, 1988, 1989), Taylor (1975), Todd *et al.* (1992), Vaurie (1967d), Wetmore & Phelps (1943).

43. Southern Helmeted Curassow

Pauxi unicornis

French: Hocco unicomme

German: Hornhooko

Spanish: Paují Unicomio

Other common names: Horned Curassow, Bolivian Helmeted Curassow

Taxonomy. *Pauxi unicornis* Bond and Meyer de Schauensee, 1939, above Bolívar, near Palmar, Yungas de Cochabamba, Bolivia.

Both members of genus have been placed, together with those of *Mitu*, and less often *Nothocrax*, in *Crax*. Has been considered a race of *P. pauxi*, with which forms superspecies (see page 315). Two subspecies recognized.

Subspecies and Distribution.

P. u. unicornis Bond & Meyer de Schauensee, 1939 - E slope of Andes in C Bolivia.

P. u. koepckee Weske & Terborgh, 1971 - slopes of Cerros del Sira, E Peru.

In 1992 a bird of undetermined race was seen in Cerros de Távora, S Peru, half way between known ranges of the two subspecies; has hence been suggested that species may be present on low Andean foothills and outlying ridges from the Cerros del Sira S into Bolivian Yungas.

Descriptive notes. 85-95 cm; male c. 3850 g; female c. 3600 g. Separated from *P. paxi* by shape of casque, deeper bill and presence of short, tightly curled, glossy crest. Peruvian race *koepckeae* has shorter helmet tilted further back, and less white on tail tips.

Habitat. Dense lower montane forest, with heavy rainfall, usually in rugged hilly country, especially between 450 m and 1200 m. In Amboró National Park, EC Bolivia, birds were found in semi-open tropical forest on steep slopes; cliffs, banks and steep ridges may help birds to escape predators by gliding downhill.

Food and Feeding. Fallen nuts of "almendrillo" (almond tree) apparently constitute major food; hard shell disintegrates, allowing birds to get at seeds. Presumably also takes other fruits fallen from trees; three types of laurel (*Nectandra*) and "negrillo" (Lauraceae), reported as food by locals. Forages mainly from dawn to 08:30 h, and from 16:00 h to dusk, or later on moonlit nights; noted to be far more active on days following moonless nights.

Breeding. Activity (nuptial calls) begins with start of rains, in Sept, in Amboró National Park. Apparently polygynous (see page 328). Only one nest has been found to date, in Oct at the same locality: a substantial structure placed 5 m up in the fork of an isolated tree, containing only 1 egg; chick rich brown, marked with black above, buff and whitish below. On basis of casque sizes, it is believed that 1st year birds participate in courting and breeding.

Movements. Presumably sedentary, but in Amboró National Park some dispersive movements have been observed at end of breeding season.

Status and Conservation. VULNERABLE/RARE. Populations only partly protected. Exceptionally poorly known; species is considered rare in Bolivia and is likely to be equally rare in Peru; apparently, it is naturally rather local in distribution, and since its discovery has never been reported as common. In Bolivia, forests in its altitude zone are rapidly being cleared; the species is persecuted by professional hunters, who are to blame for decline in numbers; also by locals, mainly for food, but, in the Yungas of Totorá, also for its helmet, which is used as a fashionable cigarette-lighter; apparently, in the Amboró area, its skewered head is used in traditional dances. An increase in numbers of the species is believed to have taken place in Amboró National Park since 1987, apparently due to reduction in hunting pressure as a consequence of wardening improvement; an estimate of 40 birds in a 100 ha plot was made in 1988 through quantitative analysis of calling data. Nevertheless, lack of funds threatens to intensify already serious problem of staff shortages; incursions continue, especially in N of park, as access very difficult to restrict, due to presence of two major roads along boundaries of park; illegal timber extraction and burning of margins are steadily reducing extent of intact habitat, and park is shortly to be reduced in size, in response to these losses. Efficient protection of the habitat of this biologically rich protected area of 180,000 ha is essential for the long-term security of the species; encroachment by settlers must be terminated; funds required. In Peru, priority should be given to establishment of a protected area in the Cerros del Sira. Equally, fieldwork in border region should be carried out in order to reveal new populations of species. Captive breeding has been achieved in the private collection of J. Estudillo, in Mexico, where more than 10 birds were present in 1993.

Bibliography. Anon. (1989a), Collar & Andrew (1988), Collar *et al.* (1992), Cordier (1971), Cox (1990), Cox & Clarke (1988a, 1988b), Estudillo López (1983, 1986), Hardy (1984), Ortiz & O'Neill (1988), Parker *et al.* (1982), Remsen & Traylor (1989), Vaurie (1967d), Wennrich (1981), Weske & Terborgh (1971).

Genus CRAX Linnaeus, 1758

44. Great Curassow

Crax rubra

French: Grand Hocco **German:** Tuberkelhokko **Spanish:** Pavón Norteño
Other common names: Great Crested/Mexican/Globose Curassow; Cozumel Curassow (*griscomi*)

Taxonomy. *Crax rubra* Linnaeus, 1758, no locality.

All members of genus form superspecies. *C. globicera* is synonym. Bogus forms "*C. chapmani*" and "*C. hecki*" described from females of rare barred morph. Birds occurring S from S Nicaragua described as separate species, "*C. panamensis*", but not now accepted even as race. Taxonomic revision of populations required, especially in S of range, as undescribed races may be found.

Species has hybridized with *C. alberti* and *C. alector*, producing fertile offspring. Two subspecies recognized.

Subspecies and Distribution.

C. r. rubra Linnaeus, 1758 - E Mexico S through Central America to W Colombia and W Ecuador.
C. r. griscomi Nelson, 1926 - Cozumel I, on coast of Yucatán, SE Mexico.

Descriptive notes. Male 87-92 cm, 3600-4800 g; female 78-84 cm, 3100-4270 g. Crest very well developed; this and prominent knob on bill separate male of present species from *C. alector*, the only other *Crax* with uniform black tail and yellow cere. Unlike any other curassow, female has three morphs; barred morph rare; intermediates of the dark and red morphs may occur, as may those of the barred and dark morphs; dark and barred morphs unknown in South American part of range, while red morph does not occur in Mexico. Immature male at first similar to dark morph female, but darker; black adult plumage acquired long

before bird fully grown; immatures lack knob on bill. Immature females of all morphs similar to adults. Race *griscomi* smaller, with some slight colour differences in females.

Habitat. Heavy rain forest in tropical and lower subtropical zones; usually occurs in lowlands, but also in foothills up to altitudes of about 1200 m, sometimes higher, e.g. in Volcán Barú, Panama, where species has been recorded up to 1900 m. In Yucatán, Cozumel I and parts of Costa Rica also occurs in seasonally drier forest, although, unlike *Penelope purpurascens*, is absent from drier forests of W Mexico. Occasionally ventures into ravines, and, if unmolested, into partially cleared areas or even plantations.

Food and Feeding. Fruits, including figs and those of *Spondias*, *Chione* and *Casimira*; usually fruits fallen from trees and taken from ground, but sometimes also those hanging on trees, mainly in low branches, or shrubs; fruits can be eaten when hard and green. Occasionally takes leaves, and also some invertebrates and small vertebrates, which are found by gleaning foliage and litter. Forages singly, in pairs or in small groups of up to 6 birds. Drinks at edges of streams.

Breeding. Feb-May in Mexico, just before rains; Mar-May in Costa Rica; Feb-Mar in E Panama, during rains; two laying females in Mar in Chocó and NW Antioquia, Colombia. Monogamous. Nest is relatively small, flimsy structure made of sticks and lined with green leaves, placed in trees usually 3-6 m above ground; one nest was constructed entirely of green leaves. Lays 2 eggs; incubation c. 32 days; chicks greyish buff with black and chestnut markings above, whitish below. Long-lived; one female lived 24 years in captivity, and bred until 23.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Rapidly disappears wherever logging roads are built into previously inaccessible forests; thus extirpated from much of Veracruz, Mexico. In Guatemala, still reported to be fairly common in E Caribbean lowlands, N Quiché and remote areas of Petén, but much reduced and threatened on Pacific slope, occurring in fragmented populations, particularly in Atitlán complex and S slopes of Volcanes Lacandón and Chiquibá. In El Salvador, species survives in El Imposible, a site proposed for protection. Maintains stable populations throughout vast areas in Nicaragua. In Costa Rica, now mostly scarce and local, with good populations persisting mainly in some national parks, including Santa Rosa, Rincón de la Vieja and Corcovado. In Panama, remains only in remote, uninhabited areas, where still seems to be fairly common, but disappears quickly, as settlement progresses; more widespread on Caribbean slope, while on Pacific slope seems to be limited to S Veraguas, W Azuero Peninsula, E Darien and some sectors of the canal zone, where very rare; in 1979 good numbers still occurred in Barro Colorado I Biological Reserve, where well protected, but apparently extirpated from Chiriquí region. In Colombia, persists only in remoter areas and along Pacific coast can not be seen near any roads. In 1986 species was feared completely eradicated from Ecuador, with no records from previous 30 years. Race *griscomi* may be near extinct; in 1965, said to survive, although sometimes hunted; a male was seen around 1990 by a researcher after months of searching. Nominate race quite common in captivity, where frequently bred; in Guatemala, small breeding programme initiated with aim of reintroducing species in areas where now extinct. One of cracids most commonly kept in captivity by locals: in Guatemala up to 100 live individuals, mainly young birds, estimated to be sold each year in local trade. CITES III in Guatemala, Costa Rica, Honduras and Colombia.

Bibliography. Alvarez del Toro (1981b), Buchholz (1991, 1992), Dickey & van Rossem (1938), Estudillo López (1986), González (1986), Griscom (1932), Haffer (1975), Heinroth (1931), Hernández & Rodríguez (1988), Hilty & Brown (1986), Honsinger (1931), Jones (1992), King (1978/79), Land (1970), Leopold (1959), Lowery & Dalquest (1951), Madariaga & Yarena de Vega (1981), Mondragón & Baez (1981), Monroe (1968), Ocampo (1981), Ortega & Aragón (1981), Ortiz (1981), Pocock (1909), Quinto (1981), Ridgely & Gwynne (1989), Ridgway & Friedmann (1946), Rutgers & Norris (1970), Saunders (1950), Schifter (1989), Sermeño (1986), Slud (1964), Smith (1966), Stiles & Skutch (1989), Sutton (1955), Taibel (1940, 1950, 1955, 1956), Todd *et al.* (1992), Vannini & Rockstroh (1988), Vaurie (1967c), Wetmore (1965), Weyer (1982), Zepeda (1981).

PLATE 34

inches 16
cm 40

45. Blue-billed Curassow

Crax alberti

French: Hocco d'Albert

German: Blaulappenhokko

Spanish: Pavón Piquiazul

Other common names: Albert's/Prince Albert's/Colombian/Blue-knobbed Curassow

Taxonomy. *Crax Alberti* Fraser, 1850, based on a cage bird of unknown origin.

All members of genus form superspecies. Form "*C. annulata*" was described from a female of the rare barred morph and an immature male of present species. Form "*C. viridirostris*", with green cere, is thought to have been described from an abnormal specimen of present species or from a hybrid of present species with another species of *Crax* (see page 315). Has hybridized in captivity with *C. rubra* and *C. fasciolata*, producing birds with green cere; also with *C. globulosa*, *Penelope pileata* and *Mitu tuberosa*. Monotypic.

Distribution. N Colombia; currently survives only in a few remnant forest patches.

Descriptive notes. 82.5-92.5 cm. Only curassow with blue cere and wattles; male lacks knob on bill, having at most slight swelling. Rare barred morph of female has more white on crest, and breast and upper belly barred black and white; only recorded on N slope of Santa Marta Mts; another morph exists, intermediate between this and normal (rufous) morph.

Habitat. Humid forest in lowlands and foothills and on lower mountain slopes in tropical zone; occurs up to 1200 m, but commoner below 600 m.

Food and Feeding. No information available

on diet. Feeds mainly on ground.

Breeding. Young recorded in Jul in area of Santa Marta Mts; birds with enlarged gonads have been taken in Feb and Apr. No further information available.

Movements. No information available; presumably sedentary.

Status and Conservation. ENDANGERED. Situation critical: action urgent when population found. Although never known to be common, species has suffered a serious decline and is now believed to be extinct throughout most of its former range, probably with only a few small populations surviving, at unknown locations. There appear to be no records since 1978, when an observation was made at Puerto Berrio, Antioquia; in 1970's species was known to survive, although becoming very rare, in Serranía de San Jacinto, Bolívar; 4 birds, presumably taken from wild, were illegally imported to Japan from Colombia in 1987. Apparently extinct from Santa Marta region, where, in humid lowlands of N coast, species possibly reached its maximum abundance; a road now runs through this area. Deforestation and hunting have been main causes of species' decline. Rapid destruction of lowland forests noted throughout range of species during 1960's, mainly associated with agriculture; at that time forest was confined to ridges at Puerto Valdivia, while in 1970's it only remained along some of deep valleys in Serranía de San Jacinto. Hunting pressure very intense in 1940's in Santa Marta region, and this was probably true for whole range. No measures known to have been taken for conservation of species. Survey of major remaining areas of forest within species' range now being planned, in order to clarify current status and distribution. Small numbers of birds kept in captivity in a few collections; breeding has been successful in several of these; these birds could serve as stock for the development of a full-scale recovery plan. CITES III in Colombia.

Bibliography. 46. Yellow-knobbed Curassow

Crax daubentoni

French: Hocco de Daubenton

German: Gelblappenhokko

Spanish: Pavón Porí

Other common names: Daubenton's Curassow

Taxonomy. *Crax Daubentoni* G. R. Gray, 1867, "Central America"? = Venezuela.

All members of genus form superspecies. Form "*C. incommoda*" was described from a rather unusual female specimen of present species. Monotypic.

Distribution. N Venezuela (N of R Orinoco) and immediately adjacent parts of Colombia.

Descriptive notes. 84-92.5 cm; male 2925-3200 g, but one bird 1625 g; one female 2325 g. Male is only *Crax* with yellow cere that has prominent knob on bill and wattle, though latter less developed than former; white tips of outer rectrices also separate it from *C. alector* and male of *C. rubra*. Female quite similar to male but lacks yellow cere, and has white markings on crest and barred breast and upper belly; the only female *Crax* with dark cere and pure white abdomen. Juvenile male essentially like adult.

Habitat. Most commonly found in gallery forests of Venezuelan and Colombian llanos;

also occurs in foothills and broken country, especially in valleys or ravines with forest surrounded by drier deciduous woodland, e.g. in Perijá Mts; often near rivers. In llanos, during dry season birds gather by remaining water courses and water-holes. Recorded between 100 m and 500 m in Venezuela; between 500 m and 1500 m in Colombia.

Food and Feeding. No information available on diet. Forages from ground to tops of trees, in small family groups, or in flocks of up to 15 birds during dry season.

Breeding. Laying in Jun in Venezuelan llanos, during early rains; two females with eggs in May in Colombia; one juvenile in Aug on W slope of Perijá Mts, Colombia. Territorial, apparently with polygynous mating system. One nest placed in a tree. Lays 2 eggs.

Movements. No information available; presumably sedentary.

Status and Conservation. Not globally threatened. Is, or was, common in llanos, at least in Venezuela, and continues to be relatively plentiful in some areas, although declining due to extensive conversion of forest to rice fields in many parts of llanos; locally distributed in rest of range. In Colombia, known only from a few scattered localities. Receives protection on several cattle ranches, e.g. Hato Piñero and Hato Masaguaral. Uncommon in collections, but has been bred in captivity. CITES III in Colombia.

Bibliography. Buchholz (1989, 1990, 1991, 1992), Hernández & Rodríguez (1988), Hilty & Brown (1986), Jones (1992), Meyer de Schauensee & Phelps (1978), Porras & Arriaga (1981), Schifter (1989), Strahl & Silva (1988, 1989), Strahl *et al.* (1988), Todd *et al.* (1992), Vaurie (1967c).

47. Black Curassow

Crax alector

French: Hocco alector

German: Glattschnabelhokko

Spanish: Pavón Guayanés

Other common names: Crested/Smooth-billed Curassow

Taxonomy. *Crax Alector* Linnaeus, 1766, "America calidiore".

All members of genus form superspecies. *C. nigra* is a synonym. Has hybridized in captivity with *C. rubra*. Race *erythronatha*, described on basis of cere colour, not unanimously accepted; birds from extreme E Venezuela are intermediates, showing rich yellow bill with some orange shading; also, in Macarena Mts, Colombia, well into range of *erythronatha*, birds have orange-yellow instead of red, bill. Two subspecies usually recognized.

Subspecies and Distribution.

C. a. erythronatha P. L. Sclater & Salvin, 1877 - E Colombia and Venezuela S of R Orinoco, except extreme E.

C. a. alector Linnaeus, 1766 - extreme E Venezuela, the Guianas and N Brazil N of R Amazon.

Descriptive notes. 85-95 cm; male 2850-3750 g; female 2400-3425 g. Crest shorter and less dense than in other species of *Crax*. Essentially lacks bill knob and wattles, with at most slightly swollen cere. Bill more slender and appears longer than in other curassows. Tail uniform black in both sexes. Only species of genus in which female is almost identical to male, but former has a few narrow white bars on crest. Races separated by cere colour.

Habitat. Humid terra firme forest and gallery forest, favouring thickets along rivers and tangled forest borders; often ventures into areas with some clearings or open ground, e.g.

along roads or in old plantations. In French Guiana, occurs in primary forest, mainly in well drained ground of inland hills. In lowlands and foothills, locally up to 1700 m.

Food and Feeding. Mainly fruits (96-51% in one study in French Guiana); also some leaves, buds and shoots (2-83% together); invertebrates, especially Coleoptera, Dictyoptera and Hymenoptera (0-33%); flowers (0-30%); and mushrooms (0-03%). In French Guiana, fruits of 80 plant species have been identified, the most important quantitatively being those of *Eugenia coffeifolia* (15-1%, dry weight), *Guarea grandifolia* (12-1%), *Guarea kunthiana* (10-7%), *Bactris acanthocarpoides* (6-9%) and *Guarea gomma* (5-9%). Forages mainly on ground, singly or in pairs. Occasionally recorded foraging alongside Grey-winged Trumpeters (*Psophia crepitans*).

Breeding. Dec-Apr, during rainy season, in Surinam; records of young in Mar and Sept in French Guiana; one female in breeding condition in Jan in Macarena Mts, Colombia. Nest is loose structure of sticks; one was a rather small platform made of good-sized sticks, lined with leaves and small pieces of bark, placed in tree c. 5 m above ground. Lays 2 eggs.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. In Colombia common, at least formerly, along E base of E Andes and in Macarena Mts; at latter locality, was considered most abundant large bird on slopes and summits of mountains, with estimate of 1 bird/c. 1-25 ha of forest. In Surinam, reported to be rather common in 1968. In French Guiana, considered at risk of extinction in medium term if strict protection measures not taken; along with Agami Heron (*Agamia agami*), reckoned to be one of the first species to disappear in areas subjected to heavy hunting pressure; has almost vanished in forests near the coast, around settled areas along large rivers, around inland villages, and wherever hunting pressure is high; optimal densities (over 8 birds/100 ha) only persist in S of country. In Brazil, fairly common in Amapá, northern Roraima and around Manaus, Amazonas; also in Pico da Neblina National Park, Amazonas, while in adjacent Cerro de la Neblina, Venezuela, was considered much less common than *Mitu tomentosa* in 1991. Quite common in captivity, where frequently bred.

Bibliography. Éard & Sabatier (1988), Éard *et al.* (1991), Forrester (1993), Glover (1977), Haverschmidt (1955, 1968), Hernández & Rodríguez (1988), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Pinto (1935, 1964), Porras & Arriaga (1981), Reinhard (1989), Schifter (1989), Siek (1985a, 1993), Snyder (1966), Strahl & Silva (1988), Thibault & Guyot (1988), Thiollay (1989a), Todd *et al.* (1992), Tostain *et al.* (1992), Vaurie (1967c), Willard *et al.* (1991).

48. Wattled Curassow

Crax globulosa

French: Hocco globuleux

German: Karunkelhokko

Spanish: Pavón Carunculado

Other common names: Yarell's/Globulose Curassow

Taxonomy. *Crax globulosa* Spix, 1825, Rio Solimes, Brazil.

All members of genus form superspecies. *C. carunculata* and *C. yarellii* are synonyms. A close relationship has been claimed between present species and *C. blumenbachii*, especially because of very similar plumage of males; but voice very different, indicating that they are not conspecific. Has hybridized in captivity with *C. alberti*. Monotypic.

Distribution. Amazon basin in Brazil, SE Colombia, E Ecuador, E Peru and N Bolivia; range very incompletely known.

Descriptive notes. 82-89 cm; c. 2500 g. Male distinguished from that of *C. blumenbachii* by larger, very well developed wattles and, especially, bill knob; also has shorter crest. Knob and wattles

sometimes yellowish, but such birds separable from male *C. daubentoni* by uniformly black tail. Female is only *Crax* with red cere and rufous belly; some individuals may show marbled pattern wings, very similar to that found in *C. blumenbachii*. Juvenile similar to adult. **Habitat.** Humid forest of the lowland lowlands, occurring up to 300 m. Despite report claiming that species prefers drier areas within its habitat and avoids swamps, everything seems to indicate an association with water, and species has been found in *várzea*, river island forest, near streams and rivers of black water, and near edges of lakes or pools. Reports from

hunters on R Jurúá, Brazil, indicate that species primarily occupies *várzea* forest at least during most of year, while sympatric *Mitu tuberosa* uses both *várzea* and *terra firme* forest. Appears to be more arboreal than other curassows.

Food and Feeding. No information available about diet. Apparently feeds less on ground than other curassow species.

Breeding. Virtually no information from the wild. Two birds captured on Ilhas Codajás, Solimes, Brazil, had enlarged gonads in Jul and Aug. Lays 2 eggs (in captivity); chicks brownish above, whitish buff below. In captivity a female laid at 1 year old, but eggs smaller than normal and did not hatch. One bird lived more than 20 years in captivity.

Movements. No information available.

Status and Conservation. INDETERMINATE. Conflicting evidence, action may be urgently required. Although very poorly known, species appears to have declined markedly and suffered widespread local extinctions. Report describing species as abundant on lower R Beni, N Bolivia, during 19th century is not reliable, as collector supposed that *C. globulosa* and *Mitu tuberosa* were different aged individuals of same species; nevertheless, old records greatly outnumber recent ones. Local people in a number of areas throughout species' range in Peru, Ecuador and Brazil talk of species having disappeared completely, or almost, mainly since 1960's; also seems to have become extinct along R Caquetá, Colombia, and no records from E Ecuador since 1982, despite much recent ornithological fieldwork in the area; intensive survey in early 1990's, including numerous interviews with local hunters throughout region, indicates species probably extirpated from Ecuador. Some birds, mostly of unknown origin, kept in captivity; traders state that birds were still obtained from local people during 1980's from remote areas of Bolivia, S Colombia, W Brazil and NE Peru. Species recently reported from along R Jurúá, Brazil, by hunters, who describe it as far rarer than *Mitu tuberosa*, but still regularly encountered; apparently also recently recorded in SE Colombia. Large number of apparently unexplored and undisturbed rivers within potentially enormous range of species suggests populations could be found in new areas. Precise reasons for extreme scarcity of recent records remain unclear, despite known problem of intense hunting pressure, with exploitation for food and for bird trade, and also reported destruction of areas of *várzea* forest in Brazilian Amazonia and alteration of riverine habitats elsewhere. No measures for conservation in wild known to have been taken; despite evident rarity, species not protected under Brazilian law; not reported from any protected area throughout range. Paradoxically, one of curassows most frequently kept in captivity; breeding achieved in a few zoos and collections. CITES III in Colombia.

Bibliography. Blake (1955), Clarke (1965), Collar & Andrew (1988), Collar *et al.* (1992), Gyldestolpe (1945, 1951), Hernández & Rodríguez (1988), Hilty & Brown (1986), Johnson (1993), Koeppke & Koeppke (1963), Novaes (1978), Ortiz, E. & O'Neill (1988), Ortiz, F. (1981), Parker *et al.* (1982), Pinto (1935, 1964), Remsen & Traylor (1989), Schifter (1989), Sick (1985a, 1993), Strahl (1991), Teixeira & Sick (1981, 1986), Todd *et al.* (1992), Vaurie (1967c).

49. Bare-faced Curassow

Crax fasciolata

French: Hocco à face nue **German:** Nachtgesichtshokko **Spanish:** Pavón Muiú
Other common names: Banded/Slater's/Fasciated Curassow; Natterer's Curassow (*pinima*)

Taxonomy. *Crax fasciolata* Spix, 1825, state of Pará, Brazil.

All members of genus form superspecies. *C. sclateri* is a synonym. "*C. estudilloi*", an unconfirmed new species described in 1977, is thought by some to have originated from a hybrid of present species with another species of *Crax* (see page 315). Present species has hybridized in captivity with *C. alberti* and members of *Penelope*. Recently, a new race, *xavieri*, described from a male of captive origin showing ochre flanks and upper thighs; possibly a plumage aberration. Three subspecies normally recognized.

Subspecies and Distribution.

C. f. pinima Pelzeln, 1870 - NE Brazil.

C. f. fasciolata Spix, 1825 - C & SW Brazil (S of R Amazon), Paraguay and N Argentina.

C. f. grayi Ogilvie-Grant, 1893 - E Bolivia.

Descriptive notes. Male 77-85 cm, 2700-2800 g; female c. 75 cm, 2200-2700 g. Only member of *Crax* with (black) bare skin around eye. Males of all three races rather similar: yellow cere with only incipient knob and without wattles, but appearing more robust than in *C. alector*; outer rectrices narrowly tipped white; some males of race *grayi* have very pale buff belly. Females of the three races vary markedly in extent of barring on upperparts, tail, breast and upper belly, and also in tone of underparts; amount of white in crest of *grayi* apparently shows considerable individual variation. Immature male similar to adult,

but with some yellow on bare skin below eye.

Habitat. Humid, semi-deciduous and gallery forests. Often recorded in woodland edges. Sometimes wanders along highways, mainly in early morning or late evening.

Food and Feeding. Fruits, usually fallen from trees and taken on the ground; also seeds and flowers; recorded feeding on the flowers of a *Tabebuia* tree. Visits salt-licks to take salt-rich earth. Forages singly or in pairs.

Breeding. Chicks in Dec. in Paraguay. Nest is a platform made of sticks, twigs, stems and leaves, lined with leaves, located in a tree; one was 4 m above ground, hidden in a tangle of creepers. Lays 2 eggs. Incubation c. 30 days.

Movements. Non-migratory in Pantanal of Mato Grosso, and probably throughout range.

Status and Conservation. Not globally threatened. Extirpated from parts of former range as result of habitat destruction and hunting. Race *pinima* considered nearly extinct in early 1970's, but still seen in reasonable numbers in forests of Rio Pindaré, Maranhão, in 1977, and in Quirém, E Pará, in 1978; recently found to be scarce around Belém, Pará; in 1990 still considered Endangered by ICBP/IUCN International Cracidae Specialist Group. Race *grayi* said to occur in fairly good numbers in Bolivia in 1986. Nominate race still relatively common in parts of Brazilian range, including Pantanal of Mato Grosso and Das Emas, Brasília and Araguaia National Parks; extinct in São Paulo. Considered rare and threatened in Argentina, except perhaps in E Formosa; known to occur in Guaycole Reserve, where in 1980's guards saw the species from time to time and 3 birds were kept captive; also present, but rare, in Reserva El Bagual (Presidente Irigoyen); apparently was also common in Misiones at end of 19th century, but rather rare or scarce during 1950's; in 1959 one bird was captured in Arroyo Uruguay-i, the only specimen taken by W. H. Partridge during 13 years of collecting in Misiones; only recent record is of a single bird observed in 1986 in Arroyo Uruzu, affluent of Arroyo Uruguay-i; possibly extinct in Santa Fé, where recorded in 1957. Only cracid in Argentina not known to occur in national parks; appears on bird list of Iguazú National Park, Misiones, but there are no documented records to support this. Locally kept in captivity. Nominate race is the most commonly kept *Crax* in collections, where frequently bred; races *grayi* and *pinima* much rarer in captivity, but both bred in private collections in Brazil and Mexico.

Bibliography. Allen *et al.* (1977), Bronzini (1943), Canevari & Cazzani (1988), Chebez (1987), Coupe (1966), Dubs (1992), Estudillo López (1986), Faust & Faust (1963), Forrester (1993), Guimarães *et al.* (1935), King (1978/79), Nardelli (1993), Navas & Bó (1988), Norez & Yzurietta (1988), Novaes (1978), de la Peña (1979, 1992), Pereyra (1950), Pinto (1935, 1964), Reinhard (1989), Remsen & Traylor (1989), Rutgers & Norris (1970), Schifter (1989), Short (1975), Sick (1969, 1979, 1985a, 1993), Straube & Bornschein (1989), Teixeira & Antas (1981), Todd *et al.* (1992), Vaurie (1967c).

50. Red-billed Curassow

Crax blumenbachii

French: Hocco de Blumenbach **German:** Rotschnabelhokko **Spanish:** Pavón Piquirrojo
Other common names: Blumenbach's/Red-wattled Curassow

Taxonomy. *Crax blumenbachii* Spix, 1825, state of Rio de Janeiro.

All members of genus form superspecies. In past, the sexes were thought to constitute two different species; male was described as "*C. rubristris*". A close relationship has been claimed between present species and *C. globulosa*, especially because of very similar plumage of males; but voice very different and precludes the possibility of their being conspecific. Monotypic.

Distribution. SE Brazil. Formerly fairly widespread from S Bahia S to NE Rio de Janeiro; currently restricted to a few scattered forest patches. One record from Bolivia repeatedly claimed to refer to present species, but erroneously.

Descriptive notes. c. 84 cm; c. 3500 g. Male has low knob on bill, but well developed wattles; crest longer than that of *C. globulosa*. Iris of adult male chestnut, of female orange-red. Female is only *Crax* that normally has wings finely barred or mottled black and chestnut, although pattern very variable individually; some females of *C. globulosa* may also show this character, but still separable, as female of present species has dark, rather than red, cere. Juvenile as adult, even before reaching same size, but crest appears higher in both sexes, as feathers less curved.

Habitat. Tall, humid primary forest, with rich undergrowth; also visits areas with lower vegetation, e.g. banks of large rivers, small floodplains, steep banks, forest tracks, treefalls and dense second-growth forest; may favour proximity of water. Occurs in lowlands, up to c. 500 m.

Food and Feeding. Fruits, usually fallen from trees and taken on the ground, but also picked off bushes and trees. Fruits can be hard and green or ripe; range from small, like berries, to so large that they must be pulled off branches and pecked to pieces once on the ground. Fruit species recorded include bicuíba (*Virola*), sapacaiá (*Lecythis*), murici (*Byrsonima*), aricanga palm (*Geonoma*), Byrbiçuba, *Eugenia*, *Ferdinandusa*, *Eschweilera* and *Pithecellobium*. Also takes tender leaves, seeds and buds, and occasionally some invertebrates, e.g. insects, centipedes and spiders (*Lycosa*). Drinks regularly, either from nearby watering places, including fresh puddles on tracks, or by taking water dripping from leaves after showers. Usually forages in pairs or in family groups up to 4 birds.

Breeding. Apparent variation in laying date from year to year, probably due to an extended breeding season each year; chicks recorded in Oct, Jan and Feb. Apparently polygamous, although the sex ratio may be affected by hunting. Nest is platform of twigs and sticks, placed in a tree between 2-6 m above ground level; an old record of a nest constructed on the ground is dubious. Usually 2 eggs, sometimes only 1; incubation 28 days. Sexual maturity reached at 2-3 years by female, which remains fertile for at least 11 years.

Movements. No information available; presumably sedentary.

Status and Conservation. RARE. Populations largely protected, but vigilance needed. CITES I. Seems to have been relatively common, at least in Espírito Santo and Bahia, during early 19th century, but in 1856 already noted as scarce in well settled areas; since then has continued to decline, so that is currently known to survive only in six or seven forest patches, with a total population guessed at a few hundred individuals at the most. Chief strongholds for the species are the Sooretama Biological Reserve and the adjacent reserve of Companhia Vale do Rio Doce, Linhares, in Espírito Santo; on the former a minimum of 26 birds were seen over period of three weeks in 1980-1981, suggesting a population of considerably more than the 60 birds supposed to occur there in 1977; in the latter 25 birds were recorded during a two week survey in 1985, and managers of the reserve believe that over 100 birds exist. No population estimates available from the three other protected areas holding the species (Monte Pascoal National Park and Una Biological Reserve, in Bahia, and Rio Doce State Park, in Minas Gerais), but numbers are likely to be very small. Has almost certainly disappeared recently from several reserves in Espírito Santo, including Fazenda São Joaquim (also known as Fazenda Klabin, now converted to the Córrego Grande Biological Reserve) where population estimated at c. 10 birds in mid-1970's; three quarters of forest remaining there at that time had been cleared by 1986. The clearance of forest at São Fidélis in 1963 led to the extinction of the species in the state of Rio de Janeiro, where it was first described. However, very recent survey work has turned up other, hitherto unknown, relict populations; at least according to local report, in unprotected forest patches (3000-5000 ha) near Camamu

and Teixeira de Freitas, Bahia. The causes of the serious decline suffered by the species are the severe forest destruction occurring throughout E Brazil and the extensive penetration of hunters and trappers into all of remaining habitat; trade has also been an enduring threat, with reports of capture in several protected areas, including Sooretama, during 1980's. Species is succesfully bred in captivity in several zoos and collections, especially in Fundação Crax, Minas Gerais, supported by Stichting Crax; this centre, which also keeps an international studbook for the species, held 258 birds in 1991, including 45 breeding pairs; 15 pairs from this stock were introduced into the Caratinga Reserve (Fazenda Montes Claros) in 1990, and another 15 into the CENIBRA Reserve, at Ipatinga, also in Minas Gerais, in 1991, although these areas may not have held the species

formerly; it is not known if the released stock in the Caratinga Reserve has survived, but c. 20 of the 30 individuals released into the CENIBRA Reserve were alive and well in 1993, and a second release of 37 birds was being prepared for the end of that year.

Class AVES
Order GALLIFORMES
Suborder PHASIANI
Family MELEAGRIDIDAE (TURKEYS)

- Large terrestrial birds, with bulky body and generally dull plumage; males have variety of appendages on brightly coloured bare skin of head and neck.
- 71-110 cm.

- North and Central America.
- Arid to mesic terrestrial environments with mixture of forest and grassland, or agriculture.
- 1 genus, 2 species, 7 taxa.
- No species threatened; none extinct since 1600.

Systematics

Turkeys are thought to have originated in Central America over 10 million years ago. There is a strong fossil record of these birds, essentially as a result of their large size and compact bones. *Rhegmenornis*, a species with pheasant- and turkey-like characteristics is known from fossils in Virginia, USA, dating back to 20-16 million years ago. Fossil records for *Meleagris* date to the Miocene, 15-8 million years ago, and the upper Pliocene, 3-2 million years ago, and have been found in diverse regions of the USA, including Virginia, Florida, Texas and California. Historically, the name "Turkey" has also been applied to cranes (*Grus*), vultures (*Cathartes*) and the Western Capercaillie (*Tetrao urogallus*). The domestic turkey arose from *Meleagris*.

Two species are recognized, the Wild Turkey (*Meleagris gallopavo*) and the Ocellated Turkey (*Meleagris ocellata*). The latter was formerly placed in a separate, monotypic genus, *Agriocharis*, but in the 1950's it was reclassified in *Meleagris*, on the basis of morphological evidence. While the plumage and mating behaviour of the two species show distinct differences, skeletal characteristics are highly similar, and eggs are nearly indistinguishable in both size and coloration. Hybridization trials involving Wild and Ocellated Turkeys, using artificial insemination, produce fertile F₁ males, supporting the contention that congeneric classification is more appropriate. No hybrids of free-living individuals have been reported.

The species are alternatively classified in their own family, Meleagrididae, or as a subfamily in the much larger Phasianidae, and there is no consensus on this matter at present. Molecular data show that turkeys are more closely related to pheasants (*Phasianus*) than to other members of Galliformes. Anatomical, immunological and genetic data have at times been used by various authorities to contend that Phasianidae or Meleagrididae is the more appropriate treatment. Hybridization tests show crosses between a domestic turkey and a Ring-necked Pheasant (*Phasianus colchicus*) produced 23% hatchlings, whereas a cross between a turkey and a domestic chicken (*Gallus*) produced 20% hatchlings. Genetic data suggest that turkeys diverged from pheasants about 11 million years ago.

Turkeys were probably distributed continuously from middle latitudes of North America to northern South America during the Pleistocene. Today, the Ocellated Turkey is isolated in the Yucatán region of southern Mexico, Belize and Guate-

mala, separated from the Wild Turkey by intervening tropical rain forest. The genus *Meleagris* is not known to exist today in South America, except as a domestic form.

Morphological Aspects

Turkeys are unmistakable, due to their large size and generally dark plumage. Other very characteristic features are the sparse feathering on the head and the robust legs.

Males stand 110 cm tall and weigh approximately 4-6 kg, in the Ocellated Turkey, or 8-10 kg, in the Wild Turkey. Females are smaller, but are still far larger than most other North American birds, at 90 cm tall and 4-5 kg. Turkeys are largely cursorial and have long, strong legs, which are dark coloured in first-year birds, but red in adults. When disturbed, turkeys prefer to run rather than fly, and will often move uphill, sometimes with their heads stretched out in front of them as they run.

In flight, turkeys show large rounded wings and broad tails. Their wings are adapted for short, powerful flight, and their ratio of body weight to wing area (1.05 g/cm²) is one of the highest among all bird species. The style of flight is characterized by a short, powerful take-off, followed by a long glide, for distance flying. A flight typically begins from a tree or a ridgetop, and often involves the bird gliding as far as a kilometre. During the short bursts of active flight, birds can attain flying speeds of 100 km/hr. Young turkeys develop their flight capabilities at two to three weeks of age.

At a distance, turkeys appear dark brown to black. Plumage is, in fact, generally brown, apart from the primaries, which are black barred with white. Albino, melanistic and erythristic (red) colour morphs are rare in the wild. Incomplete albinos are the most frequently reported variant, whereas complete albinos have not been recorded, except among domestic turkeys.

The plumage of males is iridescent and the breast feathers are tipped with black. The tail-coverts and rectrices of the Ocellated Turkey have eye-shaped, iridescent blue ocelli, which are the origin of its vernacular and scientific names.

Males possess few or no feathers on the head and neck, and the skin appears folded and lumpy, with wattles and caruncles. The frontal caruncle is a conical structure about 1 cm high, above and just behind the bill, and it can extend and droop over the side of the bill 6-8 cm. During the breeding season,

The ratio of body weight to wing area in the turkeys is one of the highest in any birds, in spite of the fact that their wings are large and rounded. This explains why most of their movement is on foot and why, even when in danger, males prefer to run away, unless closely pressed. Females, on the other hand, with a body weight about half that of the males, are better fliers and nearly always fly away from danger. The bird beats its wings very rapidly until it reaches a suitable height, and then glides down to land on a tree perch or on the ground.

[*Meleagris gallopavo silvestris*.

Photo: Marcia W. Griffen]

the wattles and caruncles of the Wild Turkey become larger and can change colour rapidly, from bright red to blue, and turquoise to white, but throughout the remainder of the year, the top of the head is bluish and the neck is red. The head and the neck of male Ocellated Turkeys are bright blue with orange caruncles.

Male Wild Turkeys have a black and grey bristle-like structure that erupts from the breast, called a beard. The beard lengthens with age, measuring about 5 cm in six month old males, and up to 25-30 cm on males over two years old. The beard is not moulted each year with all other feathers, but grows continuously, its length limited by wear, which results from frequent contact with the ground, as the turkey bends over to feed. Male turkeys also possess metatarsal spurs, each of which is composed of a bony core with a covering of keratin. The spurs grow in length and sharpness with age, reaching a maximum of about 35 mm.

Plumage in females is dull, and the breast feathers are tipped with buff. Females have more feathers on the head and neck, and much smaller caruncles and wattles than males. Feather colours are controlled by hormones, and, as a result of this, the removal of the ovaries will result in the bird developing male coloration. About 10% of female Wild Turkeys develop beards, but their structures are thinner and shorter than those of males. Females also show a small spur-button composed of keratin.

Descriptions of moulting patterns are only available for the Wild Turkey. This species moults through five different plumages: natal; juvenile; first-basic (first immature); alternate (first winter); and adult. Natal down is yellow with brown markings; juvenile plumage is brown; and adult coloration begins with the first-basic plumage at about three months of age. Primary moult is descendant (from the innermost outwards), and generally turkeys do not replace the ninth and tenth primaries in the first winter plumage. In the post-juvenile (alternate) moult, the rectrices are replaced centrifugally (in bilateral symmetry from the inside out), though complete replacement does not occur until the birds achieve full adult plumage at about 17 months. In adults, in contrast, the tail moults centripetally (from the outside in), though rather irregularly. Adults moult annually during the summer months, but because it is continuous, birds do not lose their flight ability. Ageing of Wild Turkeys is possible for up to at least three years, based on moult patterns in young birds and spur length in adult males.

The subspecies of the Wild Turkey can generally be identified by plumage colour. Those living in eastern North America,

the Eastern Wild Turkey (*silvestris*) and the Florida Turkey (*osceola*), are darker in colour, especially with respect to the tail-coverts and the terminal band of the rectrices, than the western subspecies, the Rio Grande Turkey (*intermedia*), Merriam's Turkey (*merriami*), and Gould's Turkey (*mexicana*). The colour of the tip of the tail varies from chestnut brown to white. However, there is considerable variation in this feature amongst birds occupying a given region, perhaps resulting from interbreeding with domestic turkeys, or the mixing of subspecies during early restoration programmes.

Habitat

The dominant characteristic of suitable habitat for turkeys is a combination of trees and grasses. In such areas, the proportional distribution of trees and grasses can vary widely, as long as both are present. Trees provide food and overhead cover. Turkeys roost off the ground at night, and trees provide roost-sites, but they will also roost in man-made structures. Grasses provide food directly in the form of seeds and leaves, and indirectly as habitat for insects. In eastern North America, forests with grassy clearings, or open, grassy understoreys provide good habitat. In the south-western United States, turkeys substitute powerline poles and windmills for trees, as night-time roosts. Where they are not harassed, turkeys will live in close proximity to humans, often using bird-feeders in suburban areas.

Turkeys nest on the ground, and nests are generally found where there is dense ground cover. Early in the spring, before herbaceous vegetation has grown up, nests can be found in forests near the base of a tree, in brush piles, or in shrubby forest edges. Ideal nesting habitat is provided where forest harvest has removed over 50% of the overstorey, because during the first five to ten years after overstorey removal these areas produce thick stands of shrubs such as raspberry (*Rubus*), and usually have grassed access roads for logging equipment. In such areas, females nest in the edges of the shrub cover, and use the grassy areas for feeding. It is hypothesized that turkeys will nest as close to brood habitat as possible, and that this leads them to nest in open fields, once herbaceous vegetation grows over 50 cm tall. If the first nesting attempt is disrupted, second nests are frequently located in open fields.

Turkey poults are precocial and nidifugous, leaving the nest within hours of hatching. There are three important qualities to

The habitat of the Ocellated Turkey is dense tropical forest, and it apparently prefers areas with open grassy clearings. This species has a more glossy plumage than the Wild Turkey, and its tail feathers have a series of characteristic eye-shaped spots or ocelli, from which it receives both its scientific and common names. Another distinctive feature is the presence of orange caruncles on the cobalt blue bare skin of the head. In other aspects, however, such as skeleton structure, the two species are very similar, so that generally the Ocellated Turkey is no longer placed in a separate genus, *Agriocharis*.

[*Meleagris ocellata*, Tikal National Park, Guatemala.
Photo: A. de Sostoa & X. Ferrer]

brood habitat: an environment that produces an abundance of insects, and in which poults can feed efficiently; conditions that permit feeding throughout the day without thermal stress; and, thirdly, enough cover for the chicks to hide from predators. Forests with grassy understoreys and oak or pine savannas historically provided brood habitat. Today, forest cover interspersed with pastures or hayfields provide excellent brood habitat. The structure of hayfields is such that poults can move through the vegetation but are hidden from overhead predators, while females stand tall enough to see over the top of the vegetation and detect predators at a distance.

During autumn and winter, turkeys increase their use of forest habitats and decrease their use of open areas, to take advantage of more abundant food resources and thermal cover. Turkeys will scratch down through leaves or snow to get at food, and will feed in agricultural areas, where waste grain is prevalent in farm fields after cropping and the spreading of manure. The distance turkeys will venture from forest cover appears to depend on how frequently they are harassed by predators or people. During cold weather, they prefer to roost in coniferous trees where the trees are mature enough to have large, horizontal-spreading branches.

General Habits

Turkeys are social species and spend most of the year in flocks of 6-20 individuals. An exception is during nesting, when females are solitary for much of the 41 days of egg-laying and incubation. Once the nidifugous chicks hatch, they imprint on their mother within the first 24 hours after hatching. The group of female and chicks then remains isolated from other turkeys for the first few weeks of the young birds' lives. Thereafter, different females and their broods begin to interact with increasing frequency and multiple broods are common, involving three or four adult females and their young. It is hypothesized that these multiple broods are composed of related females and their broods, although this has yet to be proved. During the winter months, flocks congregate around locally abundant food resources, and flock size may vary daily, sometimes numbering in the hundreds. Despite the size of these flocks, a well defined

social hierarchy, or pecking order, develops, and this is maintained by aggressive display and periodical fighting.

Young males leave the brood flock in mid- to late winter, just before the onset of the breeding season. Sibling males travel together and it seems that they apparently remain together for life. These young males probably do not participate in breeding during their first year, because they do not achieve sexual maturity until late in the breeding season, and also because they are subdominant to older males.

Turkey populations pioneer their way into new habitats through the dispersal of females. Young females apparently copulate in early spring and then disperse as much as 50 km away to nest. In good habitats, pioneering populations show rates of growth that can be as high as threefold per year.

Voice

Voice is yet another feature that shows marked disparity in the state of our knowledge of the two species. A total of 28 different vocalizations has been catalogued for the Wild Turkey, whereas most calls of the Ocellated Turkey have not yet been described.

In the Wild Turkey, vocalizing begins while the young bird is still in the egg, and it is thought that these vocalizations help to synchronize hatching. As social animals, voice recognition is important and turkeys are known to recognize the voices of many different individuals.

Calls range from whistles to clucks, to yelps, to drumming sounds. Most calls are variable and dependent on the context, allowing for the communication of complex messages. Only the gobble is of fixed intensity. Males gobble to attract females during breeding, when the call can be heard over 2.4 km away by human ears. The Ocellated Turkey's gobble is distinctly different from that of the Wild Turkey, and has been transliterated as "wump-wump-wump pum-pum-pum-peedle-glunk".

Food and Feeding

Turkeys begin life feeding almost exclusively on insects, but as they mature, they shift to an omnivorous diet. Young turkeys

are rarely fed by the adult and rely on a yolk reserve for the first four days of life while learning to catch insects. Studies have shown that a seven day old turkey poult requires 12 g of protein per day to meet minimum requirements, and young birds have been observed to consume 3000-4000 insects per day. At about six weeks old, poults start taking plant matter. Seeds of all sizes are consumed, from grass under 1 mm in diameter to walnuts (*Juglans niger*) over 250 mm wide. Grit is an important sideline to the diet, as it is required as an abrasive in the gizzard to help with the digestion of seeds and nuts.

Adult turkeys are opportunistic omnivores, as shown by the fact that over 100 different food items have been identified in the crop and gizzard of turkeys at one locale. Leaves of grasses and herbs, flowers and fruits, and insects are all important in the diet during the summer. Turkeys regularly scratch down through leaves and soil for food and, in autumn, large areas of the forest floor appear to have been churned by turkeys. In winter, turkeys will scratch for plant rhizomes. Waste grain from agriculture is a key food resource in northern latitudes. In areas where snow is periodically over 30 cm deep, too deep to allow turkeys to scratch down to food on the ground, the birds will remain in trees, feeding on buds. Experiments have shown that turkeys can fast for about two weeks, and can lose as much as 50% of their body weight and still recover.

Breeding

While far more work has been carried out on the Wild Turkey, the two species seem to be biologically very similar. Breeding is cued by photoperiod. Blood plasma levels of testosterone in males and prolactin in females begin increasing in late winter, and copulation and egg-laying occur in the spring. Hormonal activity is influenced by physical and social conditions. Males reach sexual maturity at about 12 months old, but may mature earlier, if food resources are good and they are not socially inhibited by older adults. Females can breed at 10 months old, but often do not do so in populations of high density. Parthenogenesis, the production of progeny from an unfertilized egg, a most unusual phenomenon in the vertebrate world, is documented in domestic turkeys, and it is suspected to occur in the wild. All offspring from parthenogenesis are male, and about 20% can produce viable sperm.

Courtship behaviour includes both vocal and visual cues. Males announce their intentions by producing a gobble call, which may attract females from a distance. The male's visual display during courtship involves him drooping the wings, and erecting and fanning the tail feathers and most of the other dorsal feathers. In the Wild Turkey, the head is held upright, and the bright red, blue and white colours on the head contrast with the black feathers; in the Ocellated Turkey, in contrast, the blue head and neck are held tightly against the back. At close range, a low puffing sound can be heard. A receptive female squats and the male mounts by climbing up on her back.

Females nest in a crude depression on the ground and lay 8-15 eggs, normally about 12; these are creamy or buff with irregular brown speckles and blotches, and measure roughly 62 x 45 mm. Eggs are laid at a rate of one every 25 hours. Incubation generally begins when the sixth egg is laid, and lasts about 28 days. Whether or not a female nests is dependent on her physiological condition, especially her fat reserves. Birds that have lost a significant amount of weight during the winter months, due to food shortages, may defer nesting for a year. If the first nest is lost, turkeys will renest, but females over two years old are more likely to renest than younger birds. Nest success is generally less than 50%, although it tends to be somewhat higher for older females. The sex ratio amongst the poults that hatch is approximately equal, which implies that annual mortality rates are also likely to be similar between the sexes. Males do not participate in any aspect of nesting or the raising of the brood.

Turkeys are capable of living more than ten years in the wild, but in most areas, survival beyond five years is unusual. Mortality is greatest in the first three weeks of life, when 50% of the young birds die, due to predation, diseases, hypothermia or accidents. Females on nests, too, are especially vulnerable to ground predators, such as foxes (*Vulpes vulpes*, *Urocyon cinereoargenteus*), skunks (*Mephitis*) and raccoons (*Procyon lotor*). The principal causes of mortality among adults are predation and hunting. Golden Eagles (*Aquila chrysaetos*), coyotes (*Canis latrans*) and bobcats (*Lynx rufus*) are common predators. Turkeys are also susceptible to a wide variety of viruses, bacteria, mycoplasmas and parasites. Histomoniasis, or black-head disease, caused by a protozoan, *Histomonas meleagridis*, is among the most frequently reported in the Wild Turkey, and *Mycoplasma gallisepticum* and *Syngamus trachea* (a nematode)

Dust-bathing is a maintenance activity to which turkeys devote a lot of time, particularly during the nesting period and before and during the moult of the body feathers. Birds often manage to cover their entire plumage with dust, by means of flapping and kicking. It seems that this rids them of parasites and keeps their plumage in good condition.

[*Meleagris gallopavo*
silvestris.
Photo: Gary W. Griffen]

Fighting between turkeys takes place periodically, and it serves to establish and maintain the pecking order amongst flock members. Fights are normally between birds of the same sex, thus forming two independent hierarchies in mixed-sex groups. The actual form of fighting is based on mutual threats, striking with the wings and kicking. It is similar in both sexes, although females tend to fight less vigorously than males.

[*Meleagris gallopavo silvestris*.
Photo: Gary W. Griffen]

The "Strutting" posture constitutes the main visual display of the male Wild Turkey during courtship. The tail and most of the dorsal feathers are erected and fanned out; the wings are lowered, with the central primaries touching the ground; the crop is inflated, thus accentuating the bright red bare skin that covers it. At moments of maximum excitement the bird makes a low sound, which has been transliterated as a "chump" followed by a "hummm"; at the same time, the tail feathers are vibrated rapidly.

[*Meleagris gallopavo silvestris*.

are considered threats to native and domestic turkey populations. Annual survival rates for adult turkeys are about 70%.

Movements

Turkeys are largely cursorial birds, roosting in trees at night and spending most of the daylight hours walking on the ground. Their style of flight is similar to that seen in the pheasants, quails and grouse (see Morphological Aspects).

Daily and seasonal movements depend on food supply and weather conditions, but often involve a bird covering several hundred hectares. On the other hand, where food resources are abundant, turkeys will remain in areas as small as a few hectares. Snow over 30 cm deep limits movements, and when it is fluffy, turkeys may remain roosting in trees for days. In some areas, turkeys show localized migration between winter and summer ranges, but these are normally movements of under 10 km. The annual home range of turkeys generally encompasses about 1000 hectares.

Copulation in the Wild
Turkey starts when a soliciting female squats in front of a strutting male, allowing him to climb on her back. The male's rounded breast actually prevents him from seeing the female during treading. It is thought that the function of the "beard", the tuft of coarse filaments that erupts from the upper breast, is to help the male guide himself towards the female for mating. The male *Ocellated Turkey* (*Meleagris ocellata*) lacks the beard, but it appears that, by holding his head further back in the strutting posture, he is able to see the female and thus orientate himself properly.

Relationship with Man

The common name Wild Turkey originated with early European colonists to North America who were familiar with the domestic turkey in Europe and now encountered the wild form. The domestic turkey of Europe had, in its moment, been derived from stock obtained in Mexico by early Spanish explorers. The name "Turkey" was in wide use in Great Britain long before species arrived, used generally as a reference to any large bird that spread its tail.

The name *Meleagris* arises from Greek mythology. Homer recounts the death of Meleager, son of the king of Calydon, in the *Iliad*. In mourning the loss of their brother, Meleager's sisters are transformed into birds, *meleagrides*. The name *meleagrides* was used by the early Greeks for certain African birds, almost certainly the guineafowl (see page 561), and the name *Meleagris* was subsequently applied inaccurately by Linnaeus to the turkeys.

The turkey has always been an important species to humans inhabiting the Americas. As a food resource, it was important because of its abundance, its relative ease of domestication and its nutritional qualities. As a wild species, the turkey has attracted attention because of its size and its social behaviour, and as a symbol of success in conservation programmes.

Native Americans relied heavily on the Wild Turkey. Archaeologists have observed that turkeys are the second most common vertebrate, after the white-tailed deer (*Odocoileus virginianus*), in the refuse collections of native Americans during the pre-Columbian era. Feathers were used to make blankets and clothing, and the fletchings of arrows; bones were fashioned into instruments for punching holes in leather or sewing needles; and spurs served as arrowheads. Native Americans in the south-west USA and Central America domesticated the turkey.

Interestingly, two sharply contrasting hypotheses have been advanced about the origins of the domestic turkey. Some authorities state that Merriam's Turkey (*M. g. merriami*), which inhabits the south-western USA, is the progenitor of the domestic turkey. Archeological data suggest that turkeys were kept by native Americans, who inhabited what is now north-western New Mexico and north-eastern Arizona in about

AD 500-700. Trade among native peoples brought the domestic turkey into Mexico and Central America.

The alternative hypothesis suggests that turkeys were domesticated in Mexico and Central America, and that trade brought them into the south-west of what is now the USA. Merriam's Turkey, instead of being the progenitor of the domestic turkey, may actually be derived from feral domestic turkeys. Uncertainty about the origins of the domestic turkey and Merriam's Turkey persists, because it is likely that Wild Turkeys were domesticated several times over the past 2000 years, and also that individual birds commonly escaped from domestic flocks.

The history of domestic turkeys in European culture began in 1519, when the Cortés expedition to Mexico brought the domestic turkey of the Aztecs back to Spain. The turkey was well established in Spain by 1530 and in Great Britain by 1541, and was part of the livestock brought by the first European colonists to North America in 1607. While American folklore describes the turkey as an important food at the first Thanksgiving held by the Pilgrims in Massachusetts, it appears doubtful that the turkey was part of the Thanksgiving tradition until 1800.

Today, the domestic turkey is probably the most widely known form of the species, and we often think of turkeys as having white plumage. However, until recently domestic turkeys raised on small farms throughout North America showed plumage similar to Wild Turkeys. Domestic and wild birds hybridized frequently, because Wild Turkeys would venture in to farmyards to mate with domestic birds, or farmers would take Wild Turkey eggs from nests to be hatched and raised by domestic hens. This mixing, in combination with selective breeding programmes, created a wide range of recognized colour morphs. In the past 30 years, poultry has become an increasingly valued kind of meat, and the turkey is the basis for a major livestock industry. Intensive breeding has produced a form of turkey that today differs markedly from the Wild Turkey. The modern domestic turkey has greater development of the breast muscle, a heavier tarsometatarsus and the all white plumage.

Wild turkeys are considered to be among people's favourite species of wildlife for both photography and hunting. Their

Clutch size in the Wild Turkey is usually of between 10 and 13 eggs, although there are records of as few as 4, and up to 17 eggs, all laid by the same female. Even higher numbers of eggs, up to 26, have been found, as a consequence of dump-laying, whereby two separate females visit the same nest at different times to lay their eggs. Incubation is carried out by the female only, and she turns the eggs periodically, normally moving several eggs with each movement of her head.

[*Meleagris gallopavo silvestris*.
Photo: Gary W. Griffen]

large size, their breeding displays, and, until recently, their rarity, have made turkeys a prize species to see. However, the social nature of these birds may be the most important reason for such attention. The vocalizing that turkeys perform, in association with the spring breeding season, is relatively easy for people to mimic. Turkeys can be drawn in to a human caller and the experience of interacting with a wild species has proved very attractive. Wild Turkey calling is so popular that contests are held throughout the USA.

Populations have reached such numbers that annual hunting seasons are allowed in most areas. Hunting generally occurs in both the autumn and spring, and involves extensive use of calls. During the autumn, hunting is allowed for either sex, and hunters seek to flush a flock, dispersing it in several directions. Hunters mimic the calls that turkeys use to re-establish contact with one another. In the spring, only the males are legal quarry and hunters mimic the calls of females to lure a male in close enough to shoot. Hunting has gained such popularity that organizations and popular magazines dedicated exclusively to turkey enthusiasts have arisen. Annual fund-raising efforts undertaken by hunters generate \$500,000 each year in support of research and management.

In the near future, the relationship of the Wild Turkey with respect to humans could change from that of a highly desired species to that of a pest. The turkey is highly adaptable, and populations have expanded into agricultural areas. Studies show that as many as 30% of farmers claim turkeys have caused significant damage to crops. More recently, turkeys have begun to inhabit suburban areas. The bird seems to be attractive until people recognize the impact a flock of these large birds has on bird feeders. Population sizes can be controlled in agricultural areas through hunting. However, such an option is less acceptable in suburban environments, presenting a management dilemma.

Status and Conservation

The Wild Turkey is one of the world's foremost examples of species conservation. Its restoration is a history replete with

failure due to ignorance, followed by astounding success built on research.

Pre-Colombian era populations are thought to have numbered in the tens of millions. Early descriptions reported individual flocks in the hundreds. Turkeys competed with Passenger Pigeons (*Ectopistes migratorius*) for beechnuts (*Fagus grandifolia*), acorns (*Quercus*) and chestnuts (*Castanea dentata*). While turkeys were numerous in the heavy forests of eastern North America, they may have reached their greatest densities in the oak and pine savanna ecosystems of the Midwest and South. Some areas probably supported autumn population densities of over 80 birds/km².

Turkeys proved especially vulnerable to hunting, when firearms were introduced by European colonists. Populations declined rapidly around the early colonies due to unregulated hunting, and the species was completely exterminated over large areas. Game laws were enacted in some parts of North America by the late 1600's, controlling the seasons of the year when hunting was allowed and the number of turkeys that could be taken. However, enforcement was inadequate, and once turkeys had been eliminated from an area, restoration proved impossible. This pattern of overexploitation was accompanied by clearing of much of the forestland in eastern North America, and, as settlement moved west, turkey populations were steadily destroyed. Only large swamps, large forests on rugged terrain, and mountainous regions, areas bypassed by settlement, continued to support turkeys. Remaining turkey populations became increasingly isolated, and estimates by conservation agencies in the early 1940's put the total population of the species at under 300,000 individuals. Most of these populations were in the southern portions of the historical range. Despite such a significant decline, no subspecies is thought to have been lost.

Little progress was made in the conservation of turkeys until the 1950's. With financial resources provided by the Pittman-Robertson Act, entailing an 11% tax on sporting arms and ammunition, enforcement of hunting laws began to improve, the government acquired and began to manage worn out farmland for wildlife habitat, and wildlife restoration programmes got under way. Gamefarm production of wildlife was the focus of the first major restoration efforts. Gamefarms

Just before night falls, the female Wild Turkey starts to brood her chicks, or poults, with her wings half open, a posture she will maintain as they sleep throughout the night. On several occasions it has been noted that poults that were not brooded during heavy rain or low temperatures died, whilst those that were protected by the mother survived. The poults are brooded on the ground for about the first two weeks, until they are able to fly up into a tree in which to spend the night. Thereafter, they roost in trees, usually beside the female for the first few weeks, or even, in the first days, under her wings, as here. As the weeks pass, roosting groups spread out, until they occupy more than one tree, usually by about the eighth week. The natal down that covers the chicks at hatching is steadily replaced by the feathers of the juvenile plumage, which cover the whole body after four weeks. However, the covering of tawny down, splotted with brown on the hindcrown and nape, remains many weeks more on the head and neck, where the contour feathers do not appear until the poult is ten weeks old.

[*Meleagris gallopavo silvestris*.

Photo: Gary W. Griffen]

The coyote (*Canis latrans*) is one of the predators capable of killing adult Wild Turkeys. Others include the bobcat (*Lynx rufus*), the puma or mountain lion (*Felis concolor*) and the Golden Eagle (*Aquila chrysaetos*). Females are particularly vulnerable on the nest during incubation, a golden opportunity for other smaller predators, such as foxes (*Urocyon cinereoargenteus*, *Vulpes vulpes*) and raccoons (*Procyon lotor*). Despite this variety of potential predators, annual survival of adult turkeys is estimated at about 70%. Not surprisingly, poults are much more vulnerable to all sorts of predators, particularly in the first two weeks, when they are still unable to fly up into trees. Eggs are also taken quite frequently by a fair number of animals. The raccoon stands out as the most typical nest robber, but nests have also been destroyed by opossums (*Didelphis virginiana*), skunks (*Mephitis mephitis*, *Spilogale putorius*), bobcats, foxes, woodchucks (*Marmota monax*) and several species of birds.

[*Meleagris gallopavo silvestris*.

Photo: Gary W. Griffen]

The current status of the Ocellated Turkey is poorly known, but it is almost certainly declining, and is as present classified as near-threatened. Habitat destruction, trapping for the live animal trade and hunting for food are the main threats.

[*Meleagris ocellata*,

hatched and raised turkeys in captivity until they were 12-20 weeks old. Releases of 330,000 gamefarm turkeys into the wild at 800 sites yielded 760 known failures; only three releases resulted in growing populations. Research showed that gamefarm birds did not possess the genetic and behavioural qualities necessary for survival and reproduction in the wild. Only the most docile wild-trapped birds were able to survive and breed in pens, and it is thought that this resulted in rapid selection for a genotype that was less suited to the wild. Further, young birds in pens did not have an opportunity to learn food and feeding habits, seasonal movements to find food resources and appropriate responses to predators.

Restoration efforts began to achieve significant success in the 1960's, as a result of three factors. First, habitat began to improve, as land historically cleared of its forests for agriculture was abandoned by farmers who found the soils to be only marginally productive. As cultivation and grazing ceased, shrubs and trees became re-established, so that a mosaic of forest, brushland and agriculture came to cover large portions of eastern North America, and this combination proved to be excellent habitat for turkeys. Interestingly, agriculture proved to be more beneficial than detrimental. In the north, the grain and dairy industries proved important, because they provided abundant food resources in the form of fields of corn and hay. The cattle industry in the south-west USA provided watering areas (livestock tanks) and roost-sites (power poles and windmills) in areas otherwise unsuitable for turkeys.

A second factor was a shift in focus of restoration efforts, away from releasing gamefarm stock towards capturing wild birds live and translocating them. Wildlife biologists developed efficient techniques for capturing wild turkeys, based primarily on the cannon-net, a large (15 x 20 m) net that could be shot over a flock of turkeys using projectiles, powered by small cannon charges. Generally, 8-12 females and 3-5 males were translocated to colonize a new area. By the mid-1970's, thousands of Wild Turkeys were being translocated annually from the remnant populations in the south to suitable habitat. Where most releases of gamefarm birds had failed to grow, most releases of transplanted wild birds grew at a rate of twofold or threefold per year. Hunting was not permitted until the populations were of sufficient size to sustain an annual harvest, and people living near these releases were so protective that losses to illegal hunting were negligible. Areas of habitat that were similar to those supporting existing populations were quickly filled and the focus shifted to research.

Science was the third critical factor in the restoration of the Wild Turkey, because it produced a phenomenal change in our understanding of the ecology of this species. New technology allowed the construction of radio transmitters small enough to be harnessed to the back of turkeys without stressing the birds. These transmitters emitted an electronic signal that enabled biologists to locate an individual turkey at any time, and often know where the bird was, without having to contact it visually and disturb its behaviour. Habitat needs could be studied directly, by tracking turkeys throughout each day, season and year. Reproduction could be studied, because females could be tracked to the nest and the number of eggs counted when she was absent. Special circuits in the transmitter allowed biologists to know quickly when a bird died and determine cause-specific mortality. By the 1970's, extensive studies involving the radio tagging of hundreds of birds were under way. Biologists examined the effects of severe winters, predation and hunter harvesting on turkey populations. Computer modelling became part of the research process in the 1980's as biologists began to unravel the complex ecology of the species.

Among the most important findings of this research were those pertaining to the habitat requirements of the Wild Turkey. In the 1950's, nearly all the remaining populations existed in areas composed of large blocks of over 10,000 ha of mature forest, and biologists believed that large forested areas were required by the bird. Research in a newly restored population in the upper valley of the Mississippi River showed why agriculture was proving to be beneficial. Turkeys could thrive in areas of interspersed forest and agriculture, and this landscape

condition was common to much of the eastern USA. Criteria for discerning suitable habitat continued to emphasize the amount of forest cover available to turkeys, until research showed that turkeys could thrive in areas with as little as 5% forest cover. That finding dramatically increased the amount of habitat available for translocation efforts.

Annual population surveys were instituted in the 1960's, to monitor the impacts of hunting and assess harvest regulations. Investigations in the 1980's and 1990's drew on these long-term data sets and showed that the dynamics of turkey populations are controlled by a complex interaction of factors. In general, modern hunting programmes in the USA have little impact on turkey populations, because of the combination of conservative hunting regulations, strict enforcement and the high reproductive potential of the turkey. The more important factors were related to nesting success and the survival of young through the first summer. Studies of turkeys, tagged as poults with very small transmitters, showed that losses of 50-90% were common. Biologists, using female turkeys imprinted on humans, observed females with young broods at close range, and showed that cold and wet weather during the first few weeks after hatching can lead to substantial losses of young birds due to hypothermia.

As a result of the changes in habitat and the conservation efforts, Wild Turkey populations have grown dramatically, reoccupying much of the former range, and thriving in places beyond historical limits. By 1990, all subspecies had shown remarkable increases in numbers, with total populations estimated at approximately 3.5 million. The species was found in 49 states in the USA, three provinces in Canada, and six states in Mexico. Efforts to restore the turkey to all of its historical range continue today, and in 1993 over 7500 individual turkeys were translocated.

Attempts to naturalize Wild Turkeys in Europe have been in progress since the 1880's. Until the 1970's these efforts were based on gamefarm stock and the experience was the same as in North America, continual failure. Translocation of wild stock began in 1978, with releases in the north-west Taunus Forest, north of Frankfurt. In five years the population grew impressively, from 14 to an estimated 150 birds.

While our knowledge of the Wild Turkey has expanded remarkably in the past 20 years, the Ocellated Turkey remains a mystery. Most research to date has been based on museum specimens and a few, limited observational studies of birds in the wild. No ecological work has been conducted, making it difficult to mount conservation programmes. Pilot studies began in 1992, with the aim of learning effective techniques for live-trapping, and also for the application of radio telemetry to this species.

PLATE 35

Family MELEAGRIDIDAE (TURKEYS) SPECIES ACCOUNTS

Genus *MELEAGRIS* Linnaeus, 1758

1. Wild Turkey

Meleagris gallopavo

French: Dindon sauvage **German:** Truthuhn **Spanish:** Guajolote Gallinazo
Other common names: Eastern Wild Turkey (*silvestris*); Florida Turkey (*osceola*); Rio Grande Turkey (*intermedia*); Merriam's (Wild) Turkey (*merriami*); Gould's Turkey (*mexicana*)

Taxonomy. *Meleagris gallopavo* Linnaeus, 1758, North America = Mexico.

Birds of NW Mexico sometimes awarded separate race, *anasta*. Six subspecies normally recognized.

Subspecies and Distribution.

M. g. silvestris Vieillot, 1817, - E North America, N to S Ontario, W to Great Plains, and S into Texas and N Florida.

M. g. osceola Scott, 1890 - Florida.

M. g. intermedia Sennett, 1879 - Kansas S into Mexico; also translocated to areas W of historical range including California, Oregon and Washington.

M. g. merriami Nelson, 1900 - W Great Plains and Rocky Mts; also translocated to areas W of historical range including Wyoming, Idaho, Oregon and Washington.

M. g. mexicana Gould, 1856 - Mexico, in mountains W of Central Plateau.

M. g. gallopavo Linnaeus, 1758 - Mexico, from Veracruz W to Jalisco, and S to Guerrero.

Introduced to Hawaii (*intermedia*), Europe, Australia and New Zealand.

Descriptive notes. Male c. 110 cm, and c. 10,000 g; female c. 90 cm, and c. 4000 g. Colours of rump feathers, and terminal band of rectrices vary from chestnut to cream. Birds in more arid environments are lighter coloured; males darker than females. Terminal band of breast feathers is black in males, buff in females. Males and c. 10% of females have pendulous, bristle-like "beard", 10-25 cm long; not moulted. Males lack feathers on the head and neck, and skin chromatophores allow variation in colour, especially during courtship, from red to white to blue. Races vary in

body size and plumage coloration: N races larger than S races; populations in E North America, (*silvestris*, *osceola*) darker, especially on tail-coverts and terminal band of rectrices, than those from W (*intermedia*, *merriami*, *mexicana*).

Habitat. Tolerant of broad range of conditions, from temperate and subtropical forest to shrub-steppe. Highest densities occur in areas containing mixture of mature hardwood forest, shrublands, and grassland or agricultural land. Nest generally situated in dense cover. Roosts above ground at night in trees or man-made structures.

Food and Feeding. Most feeding occurs on ground. Young, after leaving nest within hours of hatching, feed on insects during first 6 weeks of life. Thereafter, diet composed of seeds, fruit, tubers and leaves of plants; acorns (*Quercus*) are important food in autumn; waste grain from agriculture important during winter, in areas where snow covers ground for extended periods. Grit necessary as an abrasive substance, working in conjunction with muscles of gizzard. Scratching on forest floor during autumn is tell-tale sign of presence of species.

Breeding. Gregarious with well developed social hierarchy. Starts in early spring, with males gobbling and displaying (see page 367). Nest is shallow scrape on ground, generally in dense cover. Female isolated during nesting. Lays 10-13 eggs (c. 1 egg every 25 hours); incubation 28 days; males do not share in nesting effort. Young nidifugous, remaining with female for 9-11 months. First breeding at 1-2 years old. Nesting success averages c. 45%; species will re-nest if first nest is destroyed. Egg fertility and hatching rate over 90%; poult survival to 4 weeks old averages 35%.

Movements. Not long distance migrants, moving only 5-20 km; some altitudinal migration occurs in mountainous terrain. Seasonal movements marked by intensive use of relatively small areas of under 100 ha, with periodical shifts to other areas. Annual home range generally c. 750 ha (500-1000 ha). Movement most extensive in spring, winter snow can restrict movement to under 10 ha. Maturing females may disperse up to 50 km from natal area.

Status and Conservation. Not globally threatened. Numerous and hunted as game species throughout much of range. Populations declined as result of overexploitation, with total numbers

estimated at under 300,000 birds in 1940's. However, dramatic increase as result of conservation efforts. Research conducted during 1970's showed species tolerant of broader range of habitat conditions than previously thought. Programmes of live-trapping and transfer conducted during 1970's and 1980's, re-establishing species throughout much of historical range, so that present species is now one of most widely distributed galliforms in North America. Populations today estimated at 3,500,000 birds. Tightly controlled hunting permitted in spring and autumn throughout much of range. Situation in Mexico poorly known; may be at risk. Species has been introduced well beyond historical range, including many states of W USA (including Hawaii) and some provinces of Canada; also established in Germany, New Zealand and several small islands off SE Australia.

(1961, 1974, 1981), Wunz (1971), Zwank *et al.* (1988).

2. Ocellated Turkey
Meleagris ocellata

French: Dindon ocellé **German:** Pfauentruthuhn **Spanish:** Guajolote Ocelado

Taxonomy. *Meleagris ocellata* Cuvier, 1820, Gulf of Honduras.
Historically classified in monotypic genus *Agriocharis*, but observed differences do not appear to justify this treatment. Monotypic.

Distribution. Central America, in Yucatán Peninsula; from N Belize W to E Chiapas (Mexico), and S to N Petén (Guatemala).

Descriptive notes. 71-91.5 cm; male c. 4000 g, female c. 3000 g. Smaller, but more colourful, than *M. gallopavo*. Male lacks "beard", but both sexes have spurs, on males reaching 40 mm long. Tail-coverts and rectrices have eye-shaped, iridescent blue pattern (*ocelli*) on subterminal band; bare skin of head and neck bright blue with orange caruncles. In female, iridescent feathers greener and less bronzed than in male; female too lacks feathering on head and neck. Juvenile much duller, with pink, brown and cinnamon barring.

Habitat. Little known about habitat requirements. Most observations made near areas

characterized by combination of dense forest and open grassy areas. Species uses dense forest during most of year; greatest use of open areas in autumn, especially where agricultural crops available. Birds roost in trees at night.

Food and Feeding. Omnivorous, feeding on ground. Grass seeds and leaves, fruits and insects commonly taken; where available, corn is important component.

Breeding. Breeding begins in Mar, with males gobbling and strutting (see page ???); nesting begins in Apr. Nest is shallow scrape on ground. Average 12 eggs (8-15); incubation 28 days, with poults mostly hatching in early Jun.

Movements. Seasonal movements unknown. Limited observations suggest seasonal range of c. 300 ha. **Status and Conservation.** Not globally threatened. Until recently considered to be threatened, in category Insufficiently Known, but has now been reclassified as near-threatened. No estimates available for current population size or even relative abundance. Distribution throughout known range is patchy, because of habitat destruction and hunting pressure. In Guatemala, well protected in Tikal National Park, where birds have become accustomed to people and are rather tame; a reserve for protection of this species has been established in Petén. CITES III in Guatemala; main threats thought to be in form of live animal trade and pressure of hunting for food.

Bibliography. Blake (1977), Coliar & Andrew (1988), Davis (1972), Dickson (1992), Eaton (1992), Gaumer (1883), Land (1970), Leopold (1948), Lint (1952), Monroe (1968), Shufeldt (1914), Smithe (1966), Steadman *et al.* (1979), Storer (1993), Van Tyne (1935).

Class AVES
Order GALLIFORMES
Suborder PHASIANI
Family TETRAONIDAE (GROUSE)

- Large to medium-sized, plump terrestrial or partly arboreal birds, with short, convex bill and feathered nostrils, short legs and feathered tarsi.
- 30-90 cm.

- Holarctic, in boreal zone.
- Forest or open areas, mostly in zones of cold or cold temperate climate.
- 7 genera, 17 species, 129 taxa.
- 1 species threatened; 1 subspecies extinct since 1600.

Systematics

Although there is no doubt that the Tetraonidae constitute a natural and fairly homogeneous group within the Galliformes, it is currently a matter of discussion whether or not this small group of some 17 species should really be considered a separate family. Many authors prefer to regard the group as a subfamily within Phasianidae.

Grouse do, it is true, share many characteristics with the Phasianidae, from general body shape to basic moulting sequences, as well as many morphological and behavioural features. Recent techniques using electrophoresis of egg albumen and, particularly, DNA-DNA hybridization also point to a close affinity between grouse and pheasants, partridges and their allies. Another indication of the proximity of the two groups is the potential for hybridization; for example, the Ring-necked Pheasant (*Phasianus colchicus*), in areas of Europe and North America where it has been introduced, has occasionally interbred with at least four species of grouse.

Some special characteristics of tetraonid morphology are: feathered nostrils; tarsi without spurs, and normally with feathers instead of scales; and toes that, although not always feathered, have peculiar pectinations or small scales along either side of each toe during the winter which help the birds to climb branches and walk on the snow. Another prominent feature is the comb that most species have above the eye; these combs can be bright yellow or scarlet, and tend to develop more in males, and especially during the breeding season. In addition, males sometimes have coloured patches of bare skin on the neck, in some cases with ornamental feathers; these patches are inflated during courtship, by means of expansions of the oesophagus. All these features can be interpreted either as adaptations to cold climates or as aids to typically polygynous or promiscuous mating systems, with sophisticated courtship on the part of the males.

Fossil representatives of the Tetraonidae are known from as early as the Miocene. More specifically, the oldest known grouse, *Paleolectoris incertus* comes from the Lower Miocene of North America, while from the Middle Miocene, also of North America, we have *Tympanuchus stirtoni*, which has been assigned to a rather specialized contemporary genus. Recently however, the generic designation of these and other primitive Tetraonidae has been under question. More present day genera appear in deposits from the Pliocene, with *Tetrao* in Europe,

and the Pleistocene, with *Bonasa* and *Lagopus* in Europe and *Dendragapus* in America. On the whole, fossil records are fairly incomplete, although they do at least allow speculation about the possible origin of the Tetraonidae from primitive Phasianidae during the Miocene. They may be especially close to the snowcocks (*Tetraogallus*) with which they share a peculiar feature, the absence of the abductor muscle of the second digit.

A relatively recent origin for the Tetraonidae would be in line with the comparatively limited degree of morphological differentiation from the Phasianidae, and also with the arguments of those who consider the group merely a subfamily of Phasianidae. However, the family status of the group is defended on the grounds of a combination of morphological, physiological and behavioural peculiarities. These interrelated aspects enable the grouse to occupy an important ecological niche in the vast cold expanses of the Northern Hemisphere, where other Galliformes are virtually absent.

Their obvious adaptations to a cold climate and exclusively boreal distribution suggest that the origin of the Tetraonidae was probably in North America or Eurasia. The fossil record is too limited to decide between these two, but given the distribution of the present day representatives the American continent is perhaps slightly more likely. One genus (*Tetrao*) is exclusively Palearctic, three (*Dendragapus*, *Centrocercus*, *Tympanuchus*) exclusively Nearctic, and three (*Falcapennis*, *Lagopus*, *Bonasa*) Holarctic in distribution, whereas, in terms of species, seven are Palearctic, eight Nearctic and only two Holarctic. Nevertheless, during the period when the Tetraonidae may have originated, and until relatively recently, barely 15,000 years ago, a broad land bridge existed in the area that is now the Bering Straits.

According to various authors, three species found in boreal coniferous forests show the most primitive characteristics of the family. Generic treatment of these species has been very variable, and for some time they were generally awarded three monotypic genera, *Dendragapus*, *Falcapennis* and *Canachites*. A revision of the internal taxonomy of the grouse by L. L. Short in 1967 reduced the number of genera normally recognized from eleven to six, a move which included the amalgamation of these three genera in *Dendragapus*. Recently, however, R. L. Potapov, amongst others, has suggested that two distinct genera should be recognized, advocating the restitution of *Falcapennis*, this name having priority over *Canachites*. Thus, the

The Siberian Grouse is evidently a close relative of the Spruce Grouse (*Falcipennis canadensis*), and the two form a clear superspecies. They have commonly been placed in the genus *Dendragapus*, alongside the Blue Grouse (*Dendragapus obscurus*), but the latter is now judged to be sufficiently distinct, notably in possessing inflatable cervical sacs, to justify generic separation, as a result of which the genus *Falcipennis* has recently been resurrected for the Siberian and Spruce Grouse. According to various authors these three species are the most primitive living members of the family, the closest relatives of the ancestral form from which all grouse originated.

[*Falcipennis falcipennis*, Russian Far East.
Photo: R. Seitre/Bios]

Blue Grouse (*Dendragapus obscurus*) of America would now be split off from its traditional congeners, the Siberian Grouse (*Falcipennis falcipennis*) of Asia and the Spruce Grouse (*Falcipennis canadensis*) of America. These last two species seem to be especially close to one another as regards plumage, courtship, ecology and some other aspects, and clearly constitute a superspecies. On the other hand, the Blue Grouse is quite distinct, above all with its inflatable cervical sacs, which the other two species lack, and notable differences in the plumage of the chicks. This rearrangement into two genera has generally been well received and seems likely, in time, to receive fairly universal acceptance.

The genus *Lagopus* is not very far removed from these three species and also shares various of their primitive features. It is characterized by a special moult sequence with the plumage white in winter, by relatively small size, and by the occupation of open habitats of the Arctic or high mountains. There are three species, two of which, the Willow Grouse (*Lagopus lagopus*) and the Rock Ptarmigan (*Lagopus mutus*) are the only tetraonid species distributed throughout the Holarctic, while the third, the small White-tailed Ptarmigan (*Lagopus leucurus*), is found only at alpine altitudes in the mountains of western North America. The race *scoticus* of the Willow Grouse was long considered a different species, the Red Grouse. It is confined to the British Isles and is distinctive, among other things, in that its plumage does not change to white during the winter.

The Palearctic genus *Tetrao* was formerly divided into two genera, *Tetrao* (capercaillies) and *Lyrurus* (black grouse), each of them containing two very similar species. The capercaillies are forest dwellers of considerable size, with a western and an eastern representative, the Western Capercaillie (*Tetrao urogallus*) and the Black-billed Capercaillie (*Tetrao parvirostris*) respectively. They were probably separated during the Ice Ages, but their ranges now overlap over a large zone of the Yenisey Basin, where interbreeding often results in hybrids, evidence that their reproductive isolation is incomplete, despite the fact that their courtship rituals are quite different. The two forms of black grouse also clearly constitute a superspecies: they are smaller birds than the capercaillies and are found in more open habitats. The Eurasian Black Grouse (*Tetrao tetrix*) is wide-

spread, while the Caucasian Black Grouse (*Tetrao mlokosiewiczzi*) is the result of an isolation in the Caucasus probably dating back to the Pleistocene. As well as in size and habitat, these two species pairs differ mainly in the plumage of the males, particularly in the characteristic lyre-shaped tail of the black grouse. However, in other aspects they are very similar, for example in breeding behaviour, and cases of hybridization between the Western Capercaillie and the Eurasian Black Grouse are so common that the hybrids even have vernacular names in certain countries, for instance "rakkelfugl" in Sweden and "rackelhahn" in Germany. In fact, it has been suggested that the differences in male plumages could be interpreted largely as mechanisms of reproductive isolation, relatively recent developments aimed precisely at preventing hybridization between these two sympatric and genetically very close species.

The genus *Bonasa*, previously treated as monotypic and endemic to North America, in the form of the Ruffed Grouse (*Bonasa umbellus*), now includes two other, Eurasian species that are also small and occur in broad-leaved or mixed forests. Previously, the widespread Hazel Grouse (*Bonasa bonasia*) and the very similar Severtsov's Grouse (*Bonasa sewerzowi*) of the mountains of central China were placed in the genus *Tetrastes*. Severtsov's shows the more primitive features, at any rate in its plumage, which is not very different from that of the Siberian Grouse. On the other hand, the Ruffed Grouse is quite distinct, especially with its thick ruff in both sexes, and this species may represent a fairly recent divergence, for which reasons many authors prefer to maintain the separate genera *Bonasa* and *Tetrastes*.

Ecologically, the remaining species of grouse are characterized by a general adaptation to open habitats dominated by herbaceous plants, often in dry temperate climates. They are all confined to North America, while in Eurasia the equivalent niches are occupied by the bustards (Otididae), a family with which they share some adaptive convergence. The genus *Centrocercus* contains only one species, the Sage Grouse (*Centrocercus urophasianus*), a large bird of very distinctive appearance, and probably the most specialized member of the whole family. It seems to be most similar to the Blue Grouse, in features such as the plumage of chicks and some aspects of courtship.

The three species of the genus *Lagopus* provide one of the clearest examples of cryptic plumage in the whole of the bird world. They undergo three annual moults, one more than other grouse, and these prepare the way for three seasonal plumages, which very effectively adapt and maintain the protective function of the plumage throughout the course of the year. Even the transitional phases that appear during moults normally coincide with periods when the birds' surroundings are also changing, so that the cryptic function is perfectly continuous. The most singular of the three plumages is that worn in winter, when the birds mostly inhabit areas that are blanketed over with snow. The White-tailed Ptarmigan is completely white during winter, apart from its dark eyes and black bill and claws. The winter plumages of its two congeners are also mainly white, but their tail feathers remain predominantly dark.

[Above: *Lagopus leucurus altipetens*, Colorado, USA. Photo: Bob & Clara Calhoun/Bruce Coleman]

Below: *Lagopus leucurus leucurus*, Alberta, Canada. Photo: Hålle Flygare/Bruce Coleman]

The genus *Tympanuchus* includes three species, the Greater Prairie-chicken (*Tympanuchus cupido*), the Lesser Prairie-chicken (*Tympanuchus pallidicinctus*) and the Sharp-tailed Grouse (*Tympanuchus phasianellus*). The first two are allopatric, although their ranges almost meet, and they are so alike that there is considerable dispute as to whether or not they should really be treated as separate species. The Lesser Prairie-chicken is a little smaller and paler, and the cervical sacs of the male are reddish as opposed to yellowish in the Greater, while the song is somewhat sharper and quicker. The Sharp-tailed Grouse, previously placed in the genus *Pedioecetes*, is clearly related to its two congeners, sharing features of adult and juvenile plumage, and also of courtship. It frequently interbreeds with the Greater Prairie-chicken, producing fertile hybrids. In terms of morphology, it is perhaps the most generalized or primitive form of the three.

Taken as a whole, there is no doubt that the grouse form a homogeneous group, especially if one ignores the adornments of males in some of the polygynous species. Almost all females are very similar. The frequency with which hybrids appear in

nature between the forms that live in sympatry is further proof of this close relationship. In addition to the aforementioned crosses of the Western Capercaillie with the Black-billed Capercaillie and with the Eurasian Black Grouse, and that of the Sharp-tailed Grouse with the Greater Prairie-chicken, occasional hybridization between the Blue Grouse and the Spruce Grouse and between the Willow Grouse and the Rock Ptarmigan are recorded, as well as at least ten other combinations between species of different genera. The most frequent crosses are between the Willow Grouse and the Eurasian Black Grouse, known by the popular name of "Rype-orre" in Scandinavia.

Authors seem to agree on locating the forest genera and particularly *Falcapennis* near the evolutionary base of the group. It has been postulated that such an origin, undoubtedly stemming from primitive Phasianidae, could have been connected with the development of the so-called flora of the Turgai in the Northern Hemisphere, where deciduous forests progressively substituted tropical forests during the Tertiary. The grouse could then have become separated from the Phasianidae by means of a change in diet that allowed these sedentary birds to survive during the

The Rock Ptarmigan in summer plumage (above), and the Willow Grouse in autumn plumage (below), complete the illustration of the efficiency of protective plumage in the genus *Lagopus*. In these two species, some populations from islands or more southerly parts of their respective ranges, where snow is much less permanent, moult into their winter plumage later and retain a greater or lesser number of brownish feathers, which make their plumage more cryptic in the particular areas they inhabit. The most striking example of this is offered by the British race *scoticus* of the Willow Grouse, the well known Red Grouse, which never develops white winter plumage.

[Above: *Lagopus mutus captus*, north-east Greenland. Photo: Olivier Langrand/Bruce Coleman.

Below: *Lagopus lagopus alascensis*, Denali National Park, Alaska. Photo: John Shaw/NHPA]

winter, when they took to feeding on the buds and catkins of poplars, alders, birches and other deciduous trees. In such a case the genus *Bonasa*, almost as generalized as *Falcipennis* but essentially of deciduous forests (see Food and Feeding), is probably closest to the primitive form. Later, as the taiga expanded during the Pliocene, a period characterized by a general cooling of the climate, the genus *Tetrao* may have developed, with its adaptation to the winter consumption of conifer needles. Also in the same period, or perhaps in the even colder Pleistocene, the genus *Lagopus* may have appeared in the areas north of the forest limit. Finally, the two genera that seem the most specialized, *Tympanuchus* and *Centrocercus*, probably evolved independently at the same time as arid and deforested areas expanded in North America, towards the end of the Tertiary.

The intraspecific taxonomy of this group deserves special mention for its remarkable complexity. Although the grouse are characterized by having very few, rather similar species, their average degree of subspeciation is very high. This is related to their sedentary tendencies and the extensive ranges of many species: limited capacity of dispersal and sizeable territories

together combine to cause a reduction in the intensity of gene flow. On the other hand, although the habitat of these birds typically covers vast extensions in northerly latitudes, further south they occur in small pockets, the further south the smaller, usually coinciding with mountainous regions. As illustrated by numerous bone remains, the climatic vicissitudes of the Pleistocene imposed alternate expansions and contractions of the ranges of these birds, and northward retreats led to the formation of disjunct southern populations.

A result of this is the characteristic pattern of subspeciation in the Tetraonidae: in northern latitudes, over fairly continuous distributions they show clinal variations that make it extremely difficult to recognize valid subspecies, which in any case invariably encompass broad areas of intergradation; in the south, however, the isolated satellite populations can generally be given subspecific denominations fairly easily. The two species of Holarctic distribution, the Willow Grouse, with more than 20 proposed races, and the Rock Ptarmigan, with more than 30, offer extreme examples. In both cases the northern races are relatively few and doubtfully distinct, while a wide array

of valid subspecies occupy the southern confines of their ranges. Thus, in the Rock Ptarmigan, in the whole circumpolar belt there are six or seven races, which for some authors could well be grouped into two or three given the very slight variations, in contrast to the numerous, distinctive races resident in Scotland, the Pyrenees, the Alps, various mountain ranges of central Asia, Kamchatka, the Commander Islands, the Kuril Islands, Honshu, the Aleutians (with at least half a dozen races), Newfoundland, Greenland and Iceland.

The other species with relatively wide distribution also have quite a few geographical races: in Eurasia, the Hazel Grouse has some 12 subspecies, the Eurasian Black Grouse 7 and the Western Capercaillie 12; and in America, the Blue Grouse has 8, the Spruce Grouse 6 and the Sharp-tailed Grouse also 6. At the other extreme, up to five species of more or less restricted distribution can be considered monotypic: the Caucasian Black Grouse, the Siberian Grouse and Severtsov's Grouse in Eurasia; and the Sage Grouse and the Lesser Prairie-chicken in North America. However, while the recognition of subspecies is usually rather a subjective business, in the case of Tetraonidae there are even greater complications. Scientific descriptions have often been based on only slight variations, in many cases gradual, of size or colour, complicated by considerable individual variation and sometimes by colour morphs, as in the Ruffed and Hazel Grouse, or complex moult sequences, as in *Lagopus*. Therefore, it is not surprising that some taxonomists have opted to reduce the number of subspecies quite drastically. C. Vaurie, for example, accepted no more than three or four in the Western Capercaillie, and only four in the Hazel Grouse.

Morphological Aspects

The external appearance of the grouse does not separate them much from most other Galliformes, and, in fact, the smaller species are often popularly called "partridges", the larger ones "cocks" or "hens" and *Tympanuchus* "prairie-chickens". They are relatively plump, compact birds, with the bill, neck, wings and legs all short; the tail varies from short in *Lagopus* to moderately long in *Tetrao*.

Overall length ranges from roughly 30 cm to 90 cm. The smallest species belong to the genera *Lagopus* and *Bonasa*, and the largest to *Centrocercus* and *Tetrao*. The lightest species is Severtsov's Grouse, with some males weighing about 280 g and females around 260 g; only a little heavier is the White-tailed Ptarmigan, with both sexes weighing about 325 g. At the opposite end of the scale, the Western Capercaillie reaches weights of 5 kg and up to 6 kg in some populations, although only in males, as females rarely exceed 2 kg. This extreme dimorphism, also found in the genera *Centrocercus* and, to a lesser extent, *Tympanuchus*, is related to some peculiarities of the breeding behaviour, for it is typical of the polygamous species. On the other hand, in the monogamous genera *Lagopus* and *Bonasa* males and females are roughly the same size and weight.

Plumage is dominated by brown or grey tones and barred, spotted or scaly patterns. This clearly serves a cryptic purpose, and is typical of "prey species" such as the grouse. One of the most notable examples of such protective coloration can be seen in the genus *Lagopus*: with their three seasonal plumages and the transitional phases caused by moults, they manage to maintain excellent camouflage throughout the whole year in the variably snowy environments they inhabit.

Only the males of the genus *Tetrao* depart somewhat from this cryptic norm, with their shiny black plumage. However, much of the phaneric effectiveness of these plumages is based on the ritual exhibition of certain white areas or spots that normally remain hidden, or are not conspicuous, when the bird remains still in the semi-darkness of the forest, with its tail and wings folded. It is perhaps in order to compensate for the comparative modesty of their plumage that the Tetraonidae have brightly coloured earlobes or combs over their eyes. These combs are almost hidden by the feathers in young birds, and most of the time in females. They develop mainly in adult

males, especially during the breeding season. During courtship displays they fill with blood, which makes them swell up, sometimes so much so that the two sides almost meet over the bird's crown. The colour intensifies, often changing from yellow or orange to bright red. Males in the genera *Dendragapus*, *Centrocercus* and *Tympanuchus* also have very specialized cervical sacs, which are normally hidden under the plumage, but which can be inflated through the oesophagus to an extraordinary degree. During courtship, their colour also intensifies, due to a special flow of blood.

Also connected with mimetic functions are the colour morphs found in the genus *Bonasa*; despite a fair range of tones, there are two basic types, grey and red. In both the Hazel Grouse and the Ruffed Grouse the grey morph is commoner in the more northerly, colder parts of the range, while the red morph dominates in the south, which may be connected with the different background colours in the predominant vegetation of the two zones. For example, in a forest in Minnesota (USA) it was found that there was a relationship between the proportion of birds of the different morphs and the presence or absence of nesting Northern Goshawks (*Accipiter gentilis*): the red morph, which normally appeared in a very small minority of birds in the area, increased to 55% of the population during a period of nine years when there were no goshawks, only to drop again as soon as the goshawk re-established itself, when differential predation was clearly detected.

On hatching, the chicks, precocious and very similar in all respects to those of Phasianidae, also have extraordinarily cryptic plumage. The pattern of alternate pale and dark patches on the dense covering of down is also of some taxonomic interest. For example, one of the reasons for the Blue Grouse being placed in a different genus from the Spruce Grouse is that, while the plumage of the latter's chicks is very similar and obviously related to that found in *Lagopus*, that in the Blue Grouse is very different, and is similar to the plumage of Sage Grouse chicks.

The plumage of the Tetraonidae is also remarkable for its density and relative heaviness: an adult Hazel Grouse's plumage can suppose up to 22% of its total body mass. Undoubtedly, this is connected with a general adaptation to cold climates. Although down, as such, is not very frequent, the contour feathers have a broad down-like base and a highly developed aftershaft, both undoubtedly developments to help in thermal insulation; the aftershaft is much longer in winter than in summer. Furthermore, in the white winter plumage of *Lagopus*, the barbules have numerous peculiar vacuoles, air-filled cavities, that seem to be used for increasing insulation capacity by creating a kind of "greenhouse effect", although it has also been suggested that they could be useful for increasing the resemblance of the plumage to snow.

Both the nostrils and the tarsi are feathered. Related with the first is the lack of the membranous lid or operculum that is so characteristic of the other Galliformes. The tarsus, except for a thin strip down the back, is normally completely covered with feathers down to the base of the toes, and in *Lagopus* even the toes are feathered, as a substitution for the pectinations of the other Tetraonidae; toe feathering is probably the more recent development, as rudimentary pectinations remain in the White-tailed Ptarmigan. This feathering of the feet, much denser in winter than in summer, is the origin of the generic name, coming from the Greek *lagos*, meaning "hare", and *pous*, "foot". More than anything else, it seems to help the birds walk on the snow, in conjunction with the long toes, and claws that are almost twice as long in winter as in summer, for example 17 mm as opposed to 9 mm in the Willow Grouse. It has been calculated that each cm² of foot area corresponds to 15 g of body weight in the Willow Grouse, but to some 40 g in the rather lighter Grey Partridge (*Perdix perdix*). Experiments comparing the normal feathered feet to those without feathers have shown that the winter plumage increases the surface area of the foot by four times, and reduces sinkage into the snow by half, which must obviously result in an important saving in energy.

The digital combs of the other Tetraonidae are perhaps less effective in this respect: in the Ruffed Grouse a surface area of

Of all the North American tetraonids, the Spruce Grouse is the most closely associated with conifer forests, to such an extent that its range roughly coincides with the conifer belt that stretches right across the continent. Despite its vernacular name, this species is not limited to spruce forest, but is also found in fir and especially pine woods. Connected with this habitat preference is the fact that the Spruce Grouse is one of the tetraonids best adapted to both perching and moving about on branches of trees.

7.6 cm² has been calculated with pectinations, as opposed to 6.5 cm² without them. These pectinations are rows, sometimes double, of blunt-tipped horny appendages, 2-3 mm long, on either side of each toe. They are shed in spring and reappear during the autumn, and are thus present mainly in winter. It has been suggested that perhaps their main function is to help excavate the burrows under the snow that the birds use as thermal refuges. Their relationship with the snow could, however, be less direct: the snow forces most of the species, except the three *Lagopus*, to get by on a diet of almost exclusively arboreal source. The main use of the pectinations could therefore be to help the birds grip the branches, compensating to a certain extent for the limitation caused by having the hallux short and raised above the other toes, as in the Phasianidae but in contrast to the Cracidae. The pectinations would be a nuisance for walking in summer, when the birds feed on the ground, very often in low, dense vegetation, for example heather (*Calluna*, *Erica*). It is also indicative that in the most southerly forms, the Lesser Prairie-chicken and the race *attwateri* of the Greater Prairie-chicken, the winter combs hardly develop at all.

Moult is on the whole very similar to that in other Galliformes. Adults go through a partial pre-breeding moult in spring and a complete moult in summer, once breeding has been completed. In the latter, males begin earlier than females, sometimes a good deal earlier, as also do females that have not succeeded in rearing chicks. Primary moult is descendant, with the innermost dropping first; the rectrices are replaced centripetally, from the outermost inwards. Young birds go through a very early summer moult, two to four weeks after hatching, in connection with the precocious development of the flight-feathers. This post-juvenile moult is almost a complete moult, but the two outermost primaries, are retained until the complete moult of the following year, and, as they can easily be distinguished from the other primaries, they are very useful for helping to determine the age of trapped birds. Apart from this, young birds after their first winter usually resemble adults closely.

The members of *Lagopus* also go through another partial moult, sometimes known as the supplementary moult, beginning towards the end of the summer or in autumn, almost immediately after the complete post-breeding moult, and con-

tinuing until well into the winter. In this moult, the brown contour feathers are substituted by totally white feathers, until little by little the characteristic pure white winter plumage appears. There are, however, some exceptions. To the well known example of the Red Grouse one can add some other races that live on relatively southerly islands where the snow does not lie for long periods, for instance the Rock Ptarmigan's race *gabrielsoni* of Amchitka Island in the Aleutians, or its race *millaisi* of Scotland, as well as the race *variegatus* of the Willow Grouse inhabiting certain islands off the coast of Norway. In all these cases, moult begins later than normal, and, moreover, pigmented feathers are retained, with the result that the winter plumage is relatively pigmented rather than pure white, and thus a lot more cryptic, given the local environment. In the last of these cases, that of the Willow Grouse off Norway, it seems that the phenomenon has taken place independently on three islands, which certainly questions the validity of the subspecies in which they are all grouped. Salomonsen pointed out long ago that individuals of the Rock Ptarmigan in Newfoundland also failed to complete the winter-autumn moult if they were moved further south.

Apparently, when subjected to sudden stress, grouse can on occasions drop a whole patch of contour feathers, a phenomenon called "fright moulting". This has been recorded in many of the Eurasian and North American species, particularly in incubating females, and it may have adaptive value by allowing individuals, momentarily seized by predators, to escape, in a manner similar to that of lizards losing their tails.

Like other Galliformes, grouse have comparatively short, rounded wings, with a low aspect ratio. With 10 primaries and 15-21 secondaries, their wings fit well with the type known as "elliptical", a form useful for reaching great speeds very quickly, but with high energy investment. As in partridges, flight begins with a strong, noisy take-off, and continues with a series of rapid, rather mechanical wingbeats that alternate with fast glides on down-curved wings. Rapid take-off is an obvious mechanism for escaping from predators, and makes them, like pheasants and partridges, especially attractive to hunters. Such rapid take-off is possible due to the well developed pectoral musculature with the prevalence of white muscle fibres, which allow more intense sudden bursts of effort. The great mass of

muscle and white flesh also undoubtedly increase the value of the birds to hunters. However, these white fibres cause rapid exhaustion, so flights are typically short, as the birds soon tire. For example, it is said that if Ruffed Grouse is made to fly distances of not normally more than 100-200 m four times in quick succession, it becomes so exhausted that it is possible to catch it by hand.

Although in general grouse are reluctant to take flight, there is a certain gradation in flying ability, which improves somewhat in species of open areas. Those genera that inhabit forests, *Falcapennis*, *Dendragapus*, *Bonasa* and some *Tetrao*, hardly fly at all in their daily routine apart from occasionally to ascend or descend from trees in relation to feeding, resting or courting. In these cases it is certainly surprising the ease with which they can ascend vertically, as if in a single leap, an ability that they often incorporate in their displays in the so-called "flutter-flights". When they are surprised on the ground they usually escape by flying, but normally only to a nearby tree, where they remain still, relying on their camouflage, a strategy which many people understandably interpret as a sign of stupidity. On slopes they tend to drift downhill by flying, but normally regain higher ground by walking. It is rarely possible to see them fly above the trees, as they prefer to escape by dodging the trunks and undergrowth at medium height. In this respect they are certainly skilful, as the short wings and long tail allow easy manoeuvring, even for heavy male capercaillies. The black grouse, which are far less tied to forests, fly better than their larger relatives and can cover relatively long distances with a single straight flight, sometimes fairly high, in which a bird may glide for considerable distances with its wings spread. In Kazakhstan birds regularly move like this from the steppes to the forests, travelling distances of up to 30 km in each direction, and similar movements of some 11 km without resting have been calculated for the Greater Prairie-chicken between patches of habitat. The members of *Lagopus* also tend to be better fliers, although they normally prefer to escape on foot. The Rock Ptarmigan is especially agile in the air, and a great deal of its territorial activity is based on repeated demonstration flights, which sometimes cover 400-500 m.

There is also a wide range in abilities for terrestrial or arboreal locomotion in the different Tetraonidae. The *Lagopus* species are capable of running, with neck outstretched, back hunched and tail down, at speeds that have been compared to those of a horse trotting or of a sledge being pulled by reindeer, but their ability in trees is practically nil. At best, Willow Grouse can reach some of their food clambering clumsily among the lower branches of small birches or willows. On the other hand the Spruce Grouse, Blue Grouse and capercaillies move very well in the canopy, using their long tails to help them balance, while they move along the branches or jump from one to another, ascending spirally round the trunk. But even the most arboreal Tetraonidae, such as the small *Bonasa*, become mainly or exclusively terrestrial during almost half the year, from spring to autumn, and they are all therefore capable of walking on the ground fairly well, from the clumsy capercaillie, that generally prefers to avoid possible obstacles, to the adept Hazel Grouse, which with great ease jumps over fallen trees or makes its way through dense shrubbery.

The bill is even shorter, more robust and more curved than those of other Galliformes. The upper mandible, with a strongly convex culmen, generously covers the end of the maxilla. This type of bill, reminiscent of secateurs, is perfectly adapted to the herbivorous, mainly browsing diet that is typical of the Tetraonidae. Grouse consume mainly buds, leaves, twigs and small fruits and berries, rather than the seeds on which pheasants regularly feed. However, members of the genus *Tympanuchus*, the only insect- and seed-eaters in the family, have relatively long, slender bills, similar to those of domestic fowl and pheasants. Apart from this, there are few obvious differences between the bills of the various species, except in size.

On occasions, however, relatively small variations in the shape or length of the bill help to demonstrate the ecological segregation of different species in areas of sympatry. The most notable case is perhaps in Alaska, where during winter the three

species of *Lagopus* often coincide in the same zones: the Rock Ptarmigan, with its comparatively thin bill, is obviously the best adapted for taking the 2-5 mm long catkins and the dwarf birch buds that constitute its staple diet; the deep, broad bill of the Willow Grouse corresponds to a diet of mainly willow buds 5-15 mm long and even bigger twigs; and the White-tailed Ptarmigan, with its intermediate bill, eats large alder catkins, but also when possible those of birch and willow. On the other hand male Western Capercaillies have very large bills, that are proportionally much larger than those of females. This is not connected with sexual differences in diet, but rather with breeding behaviour: the bills are the males' principal weapons in their fights for territories and females, and, as they are conspicuously pale, they also have special value in visual signalling during courtship. This does not, however, seem to be the case, or at any rate it is less important, with its congener, the Black-billed or Small-billed Capercaillie.

The grouse's diet of plant matter, or more precisely of leaves, is fairly exceptional in the bird world; because of their very high metabolism and the lightness necessary for flight, birds tend to consume only food with a very high energy content, such as animal prey or seeds. However, the feature that best characterizes the grouse ecologically, especially in comparison with the pheasants, is their capacity to survive the winter by feeding essentially on the leaves and buds of trees, which, although easy to obtain, are very fibrous and have a very low calorie and protein content. They save a remarkable amount of energy during the winter, on the one hand because they hardly move at all, apart from the bare minimum that is absolutely necessary for feeding, and on the other hand because they shelter in tunnels under the snow (see General Habits).

Even so, a fundamental component of their adaptive strategy consists of taking maximum advantage of their relatively unnutritious plant food, especially during winter, and some of their morphological adaptations are essential for this. The most important is the comparative length of their intestines, especially of the caeca. Already in the 1950's, A. Leopold showed that in the partridges (*Perdix*, *Alectoris*) the caeca measure some 17 cm, whereas in grouse, which are only slightly larger, they reach 44 cm long on average. In fact, compared to the remainder of the intestine, the caeca measure 60-140% of its length in grouse, depending on the species, as opposed to a maximum of 50% in the pheasants, and only 35% in quails. In addition, at least in some species, gut length varies seasonally with the diet, for example in the Spruce Grouse, being some 40% larger in winter than in summer. Also, the caeca of these birds show highly developed internal crests, which greatly increase the total surface area. These are undoubtedly of immense importance for grouse, as a well developed flora of symbiotic bacteria help to break down the cellulose and thus get the best out of the plant food, as happens in the stomachs of ruminants. The caeca also carry out some food selection, so that the excessively fibrous particles in the chyme carry on through the thick intestine, while the more nutritious ones pass into the caeca to allow more time for digestion. It is quite easy to distinguish the normal or "intestinal" droppings that are deposited at short intervals throughout the day (about every six minutes in the Spruce Grouse), from the "caecal" droppings, which are larger and softer and are expelled every 24 or 48 hours, generally early in the morning.

Another function of the bacterial fermentation that takes place in the caeca is the provision of an additional endogenous heat source, which has been calculated as 11% of the basal metabolic expenditure in the case of the Willow Grouse. Lastly, it has been suggested that the caeca may recycle nitrogen from the uric acid in the urine that reaches them by retroperistalsis, starting from the cloaca. Therefore, not surprisingly, it has been possible to find a direct proportional relationship between the size of the caeca and the comparative length and harshness of the winters that each grouse species has to live through, or even between different populations within the same species.

The crop and the gizzard are also comparatively well developed in grouse. The ample crop allows them to store a great deal of food in a short time, and, as this is normally obtained

The sociability of grouse varies considerably from species to species.

Forest-dwelling species tend to have more solitary habits, whilst some of the species that live on open plains are conspicuously gregarious. The Rock Ptarmigan and its two congeners occupy an intermediate position. They breed territorially, but in autumn and winter form flocks which may contain up to 300 birds. The largest gatherings normally take place during exceptionally cold spells.

quite easily, they can therefore quickly retreat to a resting place hidden from predators. The crop of the Blue Grouse, for example, can store at least 45 g of pine needles, which is approximately half of the necessary daily intake. For this reason, two main feeding sessions per day are usually enough, one at daybreak and the other at nightfall, and the crop and the caeca complement each other so as to assure almost continuous digestion and therefore a fairly constant production of energy day and night, obviously a great advantage in cold climes. The gizzard also adapts itself to the necessities of the season, growing by as much as 75% in volume during winter, in the case of the Spruce Grouse. With an adequate load of grit, the extraordinarily muscular walls can grind into minute particles the fibrous winter food, which is quite different from the relatively tender leaves and berries taken in summer. Grit is so necessary during winter that in certain areas and years of heavy snow birds can apparently die if the grit wears out before the snow allows them to collect a fresh supply. In consequence, birds have to stock up well in grit during the autumn, and in the Western Capercaillie one study in Russia found average contents of 630-1230 stones in autumn, as opposed to only 230-300 by the end of winter.

As with the shape of the bill, the organs of the digestive apparatus are subtly adapted to the feeding preferences of the different species, thereby helping to indicate different ecological niches. In the aforementioned example of the genus *Lagopus* in Alaska: the Willow Grouse, which feeds on willow twigs and buds in winter, has a large gizzard and a relatively short intestine; the Rock Ptarmigan, which feeds on birch catkins and buds, has a long intestine and a small gizzard, in accordance with its softer, but also less nutritious, food; and finally, the White-tailed Ptarmigan, which has a variable diet, but which is generally satisfied with the hard, resinous, cone-like alder catkins that are rejected by other species, has both the intestines and the gizzard proportionally much more highly developed.

Habitat

A major ecological feature of the Tetraonidae is their perfect adaptation to cold climates. A series of morphological, physiological and behavioural adaptations allow them to thrive in environments of enormous seasonal change without resorting to long distance migration as other birds do. They are particu-

larly capable of surviving during the long, severe northern winters on a poor and limited diet, consisting basically of conifer needles or the buds of deciduous trees, almost the only vegetable food available above the frozen cap of snow.

This is, indeed, the basic difference between them and their relatives the Phasianidae, and explains how they are able to replace them ecologically in northern latitudes. Apart from this, there are no fundamental distinctions between the two groups, and grouse occupy the same wide range of terrestrial habitats as the phasianids, from densely forested to wide open areas. One possible difference lies in the extraordinary simplicity that characterizes the northerly ecosystems, with their monotonous homogeneity throughout enormous expanses of Eurasia and North America. Two aspects connected with the same question are the low number of grouse species and the vast ranges of most species.

Arctic or alpine tundra is the characteristic environment of the genus *Lagopus*. The two species with circumpolar distribution, the Rock Ptarmigan and the Willow Grouse, have different ecological requirements: the former, almost always scarcer and more localized, is adapted to the hardest and most demanding Arctic conditions, with rockier and more poorly vegetated substrate; the latter generally occupies more southerly areas or lower altitudes, usually with willow or birch undergrowth, often below the tree-line, penetrating into clearings in boreal forests and even into cold steppes, as far south as Kazakhstan. Only in Alaska and eastern Canada does the range of the White-tailed Ptarmigan overlap with that of its two congeners, and there it always occupies the highest parts of the mountains. In Eurasia, it is the Rock Ptarmigan that inhabits the high mountain habitats, from the Pyrenees to the Japan, although it is missing in most of the intermediate mountain chains, from the Carpathians and the Balkans to the Himalayas. Because of this, the recent discovery of what seems to be a tiny population in the Pamir Mountains of Tadjikistan, living at altitudes of up to 4000-5000 m during the summer, has been greeted with great excitement. In the Altai and other mountains of central Asia, the Rock Ptarmigan and the Willow Grouse occur alongside, but with the expected altitudinal segregation. However, in those areas where only one of the two occurs, habitat preferences tend to be broader, probably due to the lack of competition. Thus, in the New Siberian Islands the Willow Grouse lives in very bare Arctic areas, while in the Commander Islands the Rock Ptarmigan colonizes valley bottoms and meadows with long grass.

Scratching the head with a foot, dust-bathing and above all preening are some of the diverse comfort activities carried out by the Ruffed Grouse, and by nearly all members of the Tetraonidae, during the lengthy periods of the day which they dedicate to resting. When foraging, this species is able to fill its crop with buds very quickly, thus ensuring that feeding occupies only very brief periods. This is of importance because foraging activity, with its associated movement and noise, renders the species more exposed to the possibility of predation.

[*Bonasa umbellus*.
Photo: Leonard Lee Rue/
Bruce Coleman]

In the somewhat more numerous forest species, a clear division of habitat preferences is also visible, although there are relatively wide bands of overlap between species. Both in Eurasia and North America it is possible to order these preferences according to the different stages of forest succession. The capercaillies are related to climax forest types in Eurasia, the Western Capercaillie being most closely associated with taiga of Scots pine, and the Black-billed Capercaillie with larch taiga in Siberia. The case of the Siberian Grouse is similar, as the species is tied to the spruce and fir forests fringing the Sea of Okhotsk. In America, the boreal conifer forest is mostly occupied by the Spruce Grouse, which, in spite of its name, depends more on pine than on spruce. The Blue Grouse is also linked with coniferous forests, but above all in mountainous areas and mainly during the winter, since for breeding it prefers to use a variety of habitats, often very open ones. The species of the genus *Bonasa* also occupy very diverse forest types, although they show a marked preference for mixed coniferous and deciduous woods, and also for forests in relatively early stages of development. Not a lot is known about Severtsov's Grouse, but for both the Hazel Grouse of Eurasia and the Ruffed Grouse of America, the presence of small, fairly dense groves of deciduous trees like aspens, poplars, birches and alders is very important.

The black grouse are clearly ecotone birds, characteristic of the transition zone between forest and steppe, moor, heath or mountain thicket, with the Eurasian Black Grouse distributed over an enormous area in very varied types of forest and the Caucasian Black Grouse in a relatively narrow belt in the mountains of the Caucasus, concentrated along the tree-line. To a certain extent an ecological equivalent in North America is the Sharp-tailed Grouse, although in some areas it is even less dependent on trees, and is perfectly at home in prairies with minimal shrub cover.

The fourth and last ecological group in the Tetraonidae is found only on the plains of North America. The Sharp-tailed Grouse serves as a prelude to the other species of *Tympanuchus*, the prairie-chickens, that occupy the wide belt of grasslands in the Mid West. It seems that originally the Greater Prairie-chicken depended to a certain extent on oak forests or small woods, at least during the winter, but nowadays it is closely associated, like the bustards in Europe, with the mosaic of cultivation and small patches of grassland that occupy the old prairies. The Lesser Prairie-chicken is found in the rough con-

tinuation of this same habitat towards the south-east, in somewhat drier and warmer climates. Finally, the impressive Sage Grouse lives even further west, in a special cold dry shrub-steppe, characterized by the abundant presence of shrubs of the genus *Artemisia*.

General Habits

Grouse, in particular the forest species, are generally very unobtrusive birds, that remain well hidden and difficult to observe. Their behaviour, like their plumage, is fashioned to avoid predation as far as possible. Therefore, although they are basically diurnal birds, they usually concentrate on foraging when there is less light, at dawn and around dusk, and they spend the remainder of the day still and silent in well concealed spots. They use this time in plumage care, spending long periods preening, especially during moult. Dust-bathing is also frequent in various species, particularly during the summer, sometimes not on dry soil but on anthills, or in the wood chips left over from rotten tree trunks, but bathing in water seems to be very rare or even unknown.

Given the nature of their food (see Food and Feeding), feeding periods are typically very brief. The Ruffed Grouse, for example, without moving from one aspen, and with a rhythm of as many as 47 pecks per minute, can fill its crop with buds in just 15-20 minutes. At the other extreme is the genus *Lagopus*. In Sweden, the Willow Grouse has been calculated to forage for about six hours daily during winter, when it has to walk on the snow in search for birch buds at accessible heights, not always an easy task. On the whole, with one or two hours' foraging a day, most species can find enough food, at least during the winter, when the staple food is very simple. At other times of the year, when quality is perhaps more important than quantity, rather more time tends to be spent on feeding. In the Rock Ptarmigan in the Alps, feeding time was calculated at a daily total of four hours in midwinter, as opposed to six hours in May. Growing chicks, too, naturally spend far more time daily in feeding than adults, and they tend to feed throughout the whole day.

Feeding time is split between morning and evening, depending mainly on the comparative duration of day and night, which is extremely variable in northerly latitudes. Apparently, birds generally attempt to have some reserves in the digestive

tract at all times, and the quantity they eat at any particular moment depends on when the following feed will be. In the case of the Willow Grouse in Sweden, at 62° N, and at the end of January, two hours of foraging were registered in the morning, from 7:00 to 9:00 hours, as opposed to four hours in the afternoon, from 13:30 to 17:30 hours. Of course, at some latitudes the days are so short in winter that the birds use all the available daylight hours for feeding, and only later on does their feeding schedule again become bimodal, as in the cases of the Western Capercaillie in Finland, and *Lagopus* in Alaska. A particularly peculiar case is that of the Rock Ptarmigans on Spitsbergen, and other islands of the Svalbard group, at 77°-80° N, that do not see the light of day from the middle of November until the end of January. During the long "polar nights" the Rock Ptarmigans lose their daily rhythm, remaining continuously active.

Even while feeding, grouse remain as cautious as possible in an attempt to avoid predation. Female Willow Grouse in Norway, when moulting from white to chestnut plumage in spring, have been seen to move progressively from the snowiest areas to less snowy ones, even though this supposes changing to a diet with lower protein content, as they move from areas of willow to others of dwarf birch. In a similar way, the dark capercaillies and black grouse move to feed in the trees as soon as the first snow falls, even before the food on the ground ceases to be accessible.

Roosting and loafing areas are chosen with a view to reducing not only predation, but also as far as possible the energy costs necessary for maintaining a constant internal temperature. In steppe birds, like the prairie-chickens, these can be areas of thick, well shaded bush cover, whereas in the forest the Hazel Grouse prefers to hide behind a mass of branches in the lower part of a tree, close to the trunk. For different species of open areas, the existence of enough bushes is an important feature of habitat quality. Similarly, evergreen conifers can be very valuable during winter for species like the Hazel, Ruffed and Eurasian Black Grouse, although these species feed only on deciduous trees.

Once winter arrives, most grouse benefit from the new opportunity offered by the snow, and rest in burrows both day and night. In fact, were it not for this habit, it would be virtually impossible for them to survive in the great northern expanses where temperatures often descend to between -40°C and -50°C. At these temperatures the metabolic cost of thermoregulation is such that it is impossible to attain with the habitual low quality diet. However, inside the refuges under the snow, the temperature is about -2°C or -3°C, very near or even within the birds' range of thermoneutrality, so that an immobile bird expends practically nothing above its basal metabolic level. These refuges heat up very quickly: in the Hazel Grouse it was calculated that with a temperature of -48°C outside, the refuge reached almost 0°C in less than half an hour.

There is a certain danger that the temperature could rise too much, and the bird could get wet or the refuge collapse due to the snow melting, but to prevent this happening the grouse can open a small ventilation hole in the roof of the burrow and immediately re-establish more favourable conditions. Another potential threat is excess air humidity that could allow ice to form on the walls and impede the entrance of oxygen. It has been suggested that the feathers that cover the nostrils of grouse may serve to condense the humidity of their respiration. Also, the droppings that accumulate, besides initially creating some heat and insulating the ventral part of the body (which is also protected by the feathered tarsi), may absorb the humidity, given that their water content is extremely low, at the end of their journey through the intestines. It is interesting that they usually deposit the softest caecal droppings on top of the rest immediately before leaving the refuge in the morning.

The droppings are also useful from a practical point of view to researchers, as, due to their being expelled regularly, they can, through quantity, give a fairly precise idea of the length of time a bird has spent inside a refuge. Because of this, it is known that the use of burrows in the snow is closely related both temporally and geographically with the outside tempera-

ture. If this is only moderately low the birds spend only the night under the snow, but if it is really cold they also spend most of the day there, venturing out only as briefly as possible when it becomes essential for them to eat. On occasions, when as well as the cold there are also strong winds, they are said not to leave the burrows other than for afternoon feeding, and they may even remain inside for a couple of days. Much longer is not feasible, given the fact that they generally lack reserves of fat. An exception is the Spitsbergen race of the Rock Ptarmigan, which can acquire reserves of up to 35% of its body mass, as opposed to the maximum of 4% in the other races and species of the genus. This appears to be a clear adaptation to the climate of those islands, which in the depths of winter alternate between relatively warm periods and very cold spells when the snow freezes, restricting access to the vegetation. These fat deposits allow the birds to fast for more than 10 days; they are at their maximum in autumn, disappearing in spring.

Tunnels are dug very quickly, reputedly in about 15 seconds by the Willow Grouse, or 1 minute by the Black Grouse, although of course this depends on how hard or soft the snow is. Digging is done mainly using the feet, with their pectinations and, in *Lagopus*, the long claws they have in winter; the bill is also used, though rather little. First the bird digs vertically down, and then horizontally under the snow for some distance, normally two or three times its body length, finishing with an oval space large enough for it to stretch out in comfortably. The entrance tunnel is filled with the snow taken from farther in. In order not to leave traces, the bird normally flies a short distance to the point selected for the tunnel, or drops down to the spot from a tree. When leaving, it opens a hole directly in the roof of the chamber, sticks out its head for a moment, and then jumps out, either walking away or, especially if the snow is very soft, flying off. The thickness of the covering of snow above the chamber seems to vary between species, but in the Willow Grouse, for example, an average of 5 cm has been recorded; in one case, after heavy snow during the night, a bird moved to a second chamber slightly ahead of and above the original one, again some 5 cm from the surface.

It has been calculated that, at a temperature of -20°C, a grouse that remains under the snow saves about 20-35% of the energy it needs in order to survive. These "igloos" also serve as good hiding places from predators, although it seems that

The male Blue Grouse inflates its oesophageal air-sacs when producing its "hooting" call, one of the most characteristic elements of its territorial advertisement behaviour. A bird hoots five to seven times in fairly rapid succession, the series lasting about three seconds in all; this sequence is repeated at intervals of six to thirty-six seconds. Frequency differences have been noted between the inland and coastal races.

[*Dendragapus obscurus fuliginosus*, Glacier Bay National Park, Alaska.
Photo: Johnny Johnson/DKJ]

"Drumming" is the main system of territorial defence used by the male Ruffed Grouse. A typical "drum" consists of a flurry of strong, rapid strokes of the wings lasting five to eleven seconds, and takes place with the bird standing on a log, almost always in the same place and facing the same direction. Contrary to what has often been said, the wings do not strike the log, nor do they beat against each other, nor does the bird peck at the wood to drum. The muffled drumming sound is produced simply by air compression. In order to avoid being thrust backwards by violent beats of its wings, the bird braces its tail against the log, and clings firmly onto it with its claws.

[*Bonasa umbellus*.
Photo: J. Swedberg/Ardea]

the Great Grey Owl (*Strix nebulosa*) is an exception, with its ability to detect birds underground by means of sound location. Nevertheless, with these clear advantages, it is not surprising that most species use such burrows extensively, or that many select specific places where the snow tends to accumulate more readily during the winter, for example in forest clearings. This habit may even have favoured the evolution of some morphological features that are so characteristic of the group, such as the pectinations on the toes or the feathered tarsi and nostrils.

The different species vary considerably in terms of gregarious or solitary habits. In the genera *Falcipectus*, *Dendragapus* and *Bonasia*, it is rare to see several adults together, while at the other extreme the steppe genera *Tympanuchus* and *Centrocercus* habitually form flocks of hundreds of birds. In general, grouse are territorial and solitary birds during the breeding season, although in the species with leks, like the black grouse, the Sage Grouse and the prairie-chickens, groups of males can be seen even during this period. Such cases are all the more exceptional, given that otherwise it is the females that are generally more sociable. After breeding, which is solitary, females remain with their young for two or three months, and in various, generally solitary species, several families often join together in the autumn to form small groups. If the males do so, they tend to form a group on their own, at least those that are over a year old, and sometimes, as in *Lagopus* and the Sage Grouse, the sexes occupy different areas in winter, with males always remaining closer to the breeding grounds.

Sociability, at its height during autumn, becomes weaker throughout winter, although it is actually in exceptionally cold conditions when the largest concentrations usually occur. What with one thing and another, average group size is very variable, not only between different species, but also within the same species, according to time of year, age, sex and also geographical region, and depending on the comparative abundance of birds. For example in the Eurasian Black Grouse, the separate winter flocks of males and females normally comprise a few dozen individuals, but in certain birch forests in Siberia it has been reported that the groups reach or surpass 300-500 individuals. Perhaps the clearest function of flocks in all cases is protection against predators, due to the possibility of increased surveillance.

Voice

The repertoire of sounds produced by grouse is as wide as or wider than that of any other Galliformes, with great variability between species, sexes and ages. In particular, the profusion of non-vocal sounds in the displays of males is noteworthy. Males also use vocal sounds of several kinds, but in general it is the females that produce the greatest variety of calls, to a large extent related with breeding behaviour.

Vocal sounds are produced in the syrinx, which is of the extended tracheo-bronchial type, anatomically very similar to that of the domestic hen. The basic frequencies are the result of the different speeds of vibration of the tympaniform membranes, and they are subsequently modified, depending on the resonance qualities of the trachea and the pharynx. In general, the greater the volume of a sound tube, the lower the frequency produced, so that, for example, the larger species or fully-grown individuals are those with deeper voices, producing the lowest frequencies. Low frequency sounds are characterized by carrying farther with the same volume, which obviously enhances their effectiveness in certain aspects of territorial and sexual behaviour. In several grouse species, there are vocalizations, such as the "booming" of prairie-chickens or the "rookooing" of black grouse, that the human ear can hear at distances of 3-4 km. Another advantage of such calls is that it is more difficult for those possible predators to locate the caller. But in order to produce these types of sounds it is necessary somehow to enlarge the normal capacity of the respiratory tracts. In the Western Capercaillie, the trachea is increased in length by a third, by means of a loop at the level of the crop. More effective still is the incorporation of the oesophagus into the system of resonance, with the addition of inflatable air-sacs; in the Sage Grouse, this modification increases the total volume of the system by 25 times.

The prairie-chickens and the Sharp-tailed and Blue Grouse have similar air-sacs, which are also useful in producing visual signals during courtship. In order to inflate them, a bird must first close its bill and block the internal nostrils with its tongue, to prevent air from escaping, while at the same time the glottis is placed at the entrance of the oesophagus, which can then be filled with the air that leaves the trachea. In addition to those already mentioned, other sounds that require the use of the

The Eurasian Black Grouse is one of six grouse species in which the males form leks or arenas. At these normally very sparsely vegetated sites, a varied number of males gathers to display, attract females and copulate with them. Shortly after arriving at the lek, the males make their characteristic "rookooing" call, cocking and spreading their tails to show off the white undertail-coverts to the maximum. Two males will often face up to each other and engage in bowing duels, a type of ritualized fighting which can sometimes lead to actual fights, particularly at the height of the display period.

oesophagus are the "hooting" of the Blue Grouse, and the "cooing" of the Sharp-tailed Grouse.

Other common vocalizations, with different qualities of volume and range, made by male grouse include various grunts, hisses and cackles, as well as the high whistling song of the Hazel Grouse, which is quite similar to that of some Passeriformes. On occasions, a full range of different sounds can be heard together, such as the stereotyped song of the Western Capercaillie, with its four well defined phases appearing in a matter of barely ten seconds: first, a "tapping" reminiscent of water dripping or of sticks being knocked together; then a "drum roll" in which metallic notes accelerate until they almost merge together; next, a sudden "pop" like a bottle being uncorked; and, finally, a type of rhythmic rasping and unmusical panting, known as "whetting".

Non-vocal sounds can be produced by the wings, the tail, the feet or even by the bill, with different combinations depending on the species. Those produced by the wings are perhaps the most typical, and these are probably derived from displays in which the visual, not the acoustic, component was originally the most important, like the advertisement flights in *Lagopus* or the "flutter-flights" of other grouse (see Breeding). The speed with which the birds can beat their short wings along with the variable emargination of the remiges combine to produce diverse hissing, whirring or drumming sounds. Sometimes the wings even strike each other over the back, in the wing-clapping of the Spruce Grouse and the Siberian Grouse. Normally, these wing sounds are produced during short flights or jumps into the air, but often in the Hazel Grouse, and always in the Ruffed Grouse, when a bird is perched. In this last species, the well known "drumming" consists of the wings being beaten 50 times or so in only 5-8 seconds; they are beaten simply against the air, not against a log, as used to be thought. The procedure used by the Sage Grouse to produce "wing-rustling" is also peculiar: during display, a bird brushes its wings several times in quick succession against specialized, stiff feathers on the sides of the puffed out neck.

Characteristic sounds are produced by various species, upon opening and closing the tail abruptly, or on shaking it from side to side. In this way the Sharp-tailed Grouse produces "tail-rattling", the prairie-chickens "tail-clicking" and "snap-

ping", and the Spruce Grouse "swishing". Beating the ground rapidly with the feet, probably generating resonance inside the body, is known as "foot-stamping", and, though best known in the genus *Tympanuchus*, it is also present in a more modest version in the Spruce Grouse, the Willow Grouse and perhaps other members of Tetraonidae.

Some species can produce mechanical sounds in different ways. In the Spruce Grouse half a dozen are known: "clapping" and "drumming" with the wings; "stamping" with the feet; and "swishing" and "whooshing" with the tail. A mixture of vocal and non-vocal sounds is also quite usual, for example the Greater Prairie-chicken, along with "wing-shaking", "tail-clicking" and "foot-stamping", makes "whoop-calls", "cackle-calls" and "boomings". On the other hand, there is a certain amount of geographical variability at the subspecific level, which suggests that this could be a particularly flexible aspect of behaviour. Among other examples, "wing-clapping" is unique, within the Spruce Grouse, to the race *franklinii*, while Siberian capercaillies lack the "cork-pop" note in their song, and the frequency of "hooting" in the coastal races of the Blue Grouse is considerably higher than that of inland races.

As mentioned above, females normally have an even wider repertoire than males. Thus, while the vocalizations of male Blue Grouse are limited to only one song and two or three calls, the female has some eleven different calls. Interestingly, males and females of the monogamous genus *Lagopus* have an identical vocal range of up to 16 sounds in the case of the Willow Grouse, a similar number to those registered in Phasianidae for species such as the Chukar (*Alectoris chukar*) or the Ring-necked Pheasant. Some of the calls have a clear enough function, for example the "assembly call" that is used for gathering the chicks together, or "hawk alarm", which indicates the presence of a flying predator, but in some cases different authors have different interpretations. There is considerable scope for further investigation, and this could well lead to the discovery of new calls and new interpretations even in the better known species.

Vocalizations develop throughout an individual's life. Chicks have only a few, very specific calls, sometimes only two. One is for contact in normal situations, a "contact call", "contentment call" or "peeping". The other, a "lost call", "distress call" or "wailing", is used when a chick feels lost or

The male Sharp-tailed Grouse performs several courtship and territorial defence displays. The most complex is known as "tail-rattling" or "dancing". With the wings outspread and the neck feathers bristled up to expose the bare purple skin patch, the bird vibrates its raised tail producing a frictional rattling sound; at the same time, it moves forward with rapid series of steps, normally following a curving route. When two or more males coincide at a dancing ground, their "tail-rattling" displays are often highly synchronized.

threatened. Both are immediately answered by the mother, either vocally or in some other way.

Food and Feeding

The diet of most grouse species is fairly well known. The fact that they are popular game birds has obviously been a significant factor in the motivation of many detailed studies that have been carried out. The specialized vegetarian diet of the group stands out, even more so than in the other Galliformes. Animal food is of minimal importance, except in the first few days, or at most the first weeks, of life.

In order to understand the feeding ecology of these birds, it is essential to consider their vegetarian diet within the framework of the extreme seasonal variation that dominates their habitats. During winter, the simplicity of northern ecosystems is especially marked, so that grouse are forced to adopt amazingly monotonous diets. For example, throughout most of their respective ranges for several months, capercaillies in Eurasia and Blue and Spruce Grouse in America eat practically nothing but pine needles or those of other conifers. Similarly, Ruffed Grouse specialize on aspens (*Populus*), Willow Grouse on willows (*Salix*), black grouse on birches (*Betula*) and Sage Grouse on sagebrush (*Artemisia*). These habits, of which hunters are naturally well aware, have influenced some of the vernacular names applied. In addition to the examples already mentioned of Spruce, Willow and Sage Grouse, there are Hazel Grouse, "Pine Grouse" for the Blue Grouse, "Cedar Partridge" for the Spruce Grouse, "Popple Partridge" for the Ruffed Grouse, "Heath Hen" for a race of the Greater Prairie-chicken, and many more. The presence or absence of the relevant plants can often affect the distribution of the different species (see Habitat).

Many of the most important plants in winter are conifers (*Pinus*, *Picea*, *Abies*, *Tsuga*, *Larix*, *Juniperus*), or members of a small group of interrelated families of primitive angiosperms, including Salicaceae (*Salix*, *Populus*), Betulaceae (*Betula*, *Alnus*) and Corylaceae (*Corylus*, *Carpinus*, *Ostrya*), all of which are fairly abundant in the cool temperate, northern eco-

systems. These are all trees or bushes, often the only plants that emerge above the layer of snow during the winter months. From these plants, the grouse consume mainly the buds of broad-leaved trees and the needles and buds of conifers. Towards the end of winter, the male catkins of deciduous trees usually become very important.

In spring, the melting of the snow normally allows access to ground vegetation, and with this the variety of the diet increases somewhat, although buds and catkins normally remain of prime importance for some considerable time. Some species eat early flowers, including buttercups (*Ranunculus*), anemones (*Anemone*) and primroses (*Primula*). However, the most radical change usually takes place well into spring or even in summer, when the undergrowth plants fruit. The tender leaves and berries of plants such as *Vaccinium* and *Empetrum*, or in mountainous regions *Rhododendron* or *Arctostaphylos*, normally form the bulk of the diet, along with lesser quantities of some Rosaceae, notably *Rubus*, *Ribes*, *Dryas*, *Fragaria*, *Prunus* and *Amelanchier*.

During the summer, most species also take insects and other arthropods, although normally only in very low proportions. In this aspect, the prairie-chickens constitute a notable exception, as both species eat many insects, above all grasshoppers, to the extent that the proportion of animal food can surpass 50% of the diet in the summer months; in the Lesser Prairie-chicken, a proportion of 40-50% insects has actually been calculated for the year as a whole. In any case, in all species the importance of arthropods seems to be considerable during the first stages of chick development, probably due to the high-quality proteins they contain. In the first days of life, chicks eat mainly ants and their larvae, grasshoppers, beetles and sometimes caterpillars and spiders. Nevertheless, they soon switch to a mainly vegetarian diet. One study of the Ruffed Grouse gave 70% insects in the first two weeks, as opposed to 30% in the third and fourth weeks. Similarly, Sage Grouse chicks were found to take 60% insects in the first week, with progressively smaller proportions in successive weeks, until only 5% were consumed in the twelfth week.

During autumn, the importance of berries in the diet can last for some time, although fairly early on, from about Sep-

The ground display of the male Western Capercaillie is both the most elaborate and the most characteristic form of territorial advertisement that this species performs. It normally takes place after the bird has called from a perch in a tree (tree display), and then descended to the ground with noisy flight (flight display). Once on the ground, having first adopted the "Thin-necked Upright" posture, it begins its characteristic song, which consists of four distinct phases. The neck and head are thrust upwards, thus causing the "beard" to stick out in front, while the tail is fully fanned and raised and the wings drooped somewhat, so that the conspicuous white shoulder patch is completely revealed. This display may be performed by one bird alone, or in the company of other males.

[*Tetrao urogallus*.

Bruce Coleman]

The strutting sequence of the male Sage Grouse, a lek-forming species, is one of the most spectacular displays performed by any grouse. It is performed with the long, pointed tail fully fanned and raised almost vertically. The movements and sounds of the display are highly stereotyped, and include a series of forward steps, rotating movements of the wings across the stiffened feathers on the sides of the breast and neck, producing a brushing sound, and inflation of the oesophagus, with associated expansion of two olive green skin patches on the foreneck.

tember or October, birds begin to consume pine needles and buds. This is perhaps in order to allow the slow development of the intestinal bacterial flora that must be prepared for when the first snow falls, when the austere winter diet is rapidly imposed. Even captive birds display this spontaneous autumn change in their feeding behaviour. For those forms that specialize on conifers, larches can be very important during the transitional stage, before they lose their leaves. Sometimes mushrooms too can be of some importance in autumn, for instance in the Ruffed and Spruce Grouse.

On the other hand, in contrast to the feeding preferences of most of the Phasianidae, seeds are of very limited importance to grouse. In the Ruffed Grouse, it has been seen that even the seeds ingested along with fruit pass through the digestive tract more or less intact and often manage to germinate in the excrements. Once again the prairie-chickens provide the exception, as they are mainly seed-eaters, especially during winter, when they often prefer to eat crop plants like sorghum or maize. This winter consumption of seeds, obviously impossible for the species that live in more northerly regions with more snow, is a fundamental adaptation of the prairie-chickens to life in grasslands, and in this habit they differ significantly from the Sage Grouse, which is tied to the leaves of sagebrush.

In spite of the fairly notable diet specialization of the grouse, occasional interesting geographical variations exist between the various different species. Sometimes these are due simply to the absence of the favourite plant or plants in a certain region. In the Cantabrian Mountains of northern Spain, where the present oceanic climate hampers the development of coniferous forests, the Western Capercaillie bases its winter survival on holly (*Ilex aquifolium*), whereas in the nearby Pyrenees it is able to stick to its habitual food source, pines. On occasions, their special diets seem to be affected by competition from similar species. For example, in areas like Alaska where the Willow Grouse and Rock Ptarmigan coincide, the former consumes mainly willow and the latter birch, but in Iceland, where it is alone, the Rock Ptarmigan hardly touches birch, other than when the snow covers the smaller willows.

As a vegetarian specialization is unusual amongst birds, there has been considerable attention regarding the nutritious value of the food taken by grouse. A recurring question that

has interested many workers is whether their winter food provides enough nutrition to allow them to remain in good condition, or simply to survive. It has been seen, for example, that the calorific value of the aspen buds that constitute the only winter food in many areas of the Ruffed Grouse is only about a fifth of that generated by normal fodder for domestic birds, and is not very different from the value obtained for the pine needles that other Tetraonidae consume. In some cases, it has been proved mathematically that it is indeed possible for the birds to satisfy their needs by processing relatively large quantities of such food, but apparently within fairly strict limits. In the Blue Grouse, captive birds remain in good condition if they consume around 170 g daily of Douglas fir needles, but they lose weight if they are given Engelmann spruce, the metabolizable energy of which, per gram of dry material, is approximately 64% of that of the fir. Could they not then simply make do with taking a larger quantity of spruce needles? The answer may be "no". The task of processing more than a quarter of a kilo of needles in a day could well be beyond the capacity of birds which on average weigh little more than a kilogram. There must be a limit somewhere to the prodigious adaptations of their digestive system (see Morphological Aspects)!

In accordance with this is the high degree of food selection recorded in many field observations. Grouse not only clearly prefer one species to another, but even show preference for certain parts of the trees, or they may prefer some particular trees to others. The Ruffed Grouse, for example, chooses the tallest branches of an aspen, where the buds are known to average larger and more nutritious. They also prefer older, gnarled, sick trees or those growing in unusual sites, in other words, trees subjected to some type of "stress" that causes them to produce more buds, the principle behind the pruning of fruit trees or rose bushes. It has long been known that in both the Western Capercaillie of Europe and the Spruce Grouse of America there are birds that spend almost all winter in a single pine tree, even though their browsing may leave the tree conspicuously damaged, while neighbouring trees may remain intact.

Also in accordance with a very low-energy diet, there are certain facets of the winter behaviour of the Tetraonidae that seem to save energy (see General Habits). The morphology of

Ritualized or actual fighting in defence of a territory is fairly common between males of the Greater Prairie-chicken. These confrontations, and also those in the other two members of the genus *Tympanuchus*, are characterized by short jumps into the air in which a bird attempts to strike its opponent with the bill and claws, and sometimes with the wings. A squatting posture with the tail cocked and a number of aggressive calls are also typical features of such combat.

[*Tympanuchus cupido*.
Photo: Annie Griffiths/
DRK]

these birds and in particular the thickness of their plumage allows their lower critical temperature, the minimum threshold of their thermoneutral range, to be about 0°C, as opposed to the 18°C that is normal in birds. In the Willow Grouse it can even be as low as -6°C. It seems that these low levels accompany metabolic rates at rest that, using the normal allometric equations, are quite a lot higher than in other birds for instance about 24% in the Blue Grouse and 31% in the Eurasian Black Grouse. But below these thresholds the metabolic expenditure necessary to maintain a constant internal temperature increases greatly, and with it the need for food. In the Eurasian Black Grouse, for example, it has been calculated that a bird weighing 1 kg requires 937 KJ a day at -5°C, as opposed to 1293 KJ at -25°C. Taking as an example a normal diet in the Alps, comprising 75% leaves of *Picea* and 25% leaves of *Vaccinium*, this means that at -5°C the bird needs to fill its crop, which can hold 120 g of food, four times a day, but at -25°C it needs to do so six times, or even seven if one allows for the greater metabolic expenditure implied by the increase in activity necessary for obtaining so much food. Naturally their digestive system is not capable of such a feat. For this reason, among other things, the refuges under the snow, where birds can remain for long stretches at rest without losing heat, are so important.

Another crucial moment in the calendar for grouse is spring, when breeding success could be affected if the food supply were somehow deficient. In these birds, the low capacity for storing fat reserves does not make it feasible for females to prepare in advance for egg formation, which, instead, they have to carry out as they go along. It depends on the conditions that they encounter each spring, for example how early or late the snow melts. Besides, the deficiencies can be in terms not only of energy, but also of nutrition. In the Scottish Red Grouse, for example, it has been established that both breeding success and population density are higher on those moors that are on alkaline soils. The reason seems to be that their staple food, the heather *Calluna vulgaris*, has a higher nutritional value on these soils than when it grows on acid ones, and has a higher content of proteins and perhaps also of potassium, phosphorus and other elements. Also, in spring females prefer to eat in artificially fertilized areas, and generally in those where the heather

has a higher nitrogen content, although this does not seem to be a particularly precise measure of the availability of protein. A selection is also made not only of the species of plant, but of plants of different ages or even of parts of plants, such as new buds, that are especially rich in nutrients; such selection has been proved for the Red Grouse, the Spruce Grouse, the Ruffed Grouse and other species.

Food quality can also vary from one year to the next, depending on the different resin content that certain plants are capable of producing, seemingly as a defence against browsing animals. In the Ruffed Grouse's favourite aspens, there are years when the flower buds contain so much resin that the birds clearly avoid them, perhaps because there are phenolic compounds in the resin that greatly inhibit the activity of the microbial intestinal flora. Some authors have even suggested that this could be the source of the fluctuations in numbers that many grouse species suffer (see Breeding), although this is an extremely complex matter that is still subject to considerable debate.

Breeding

One of the most significant and well known aspects of the biology of the Tetraonidae is the high frequency of polygynous mating systems. In these, males compete at sites known as "leks" or "arenas" to win the favours of the females, but they do not assist them at all in any of the breeding tasks. This conduct, besides being very spectacular, is comparatively rare in birds, with other notable examples in the Ruff (*Philomachus pugnax*), the Great Bustard (*Otis tarda*), the Kakapo (*Strigops habroptilus*), the Village Indigobird (*Vidua chalybeata*) and several manakins (Pipridae), cotingas (Cotingidae) and birds of paradise (Paradisaeidae), as well as a few other cases. But amongst the Tetraonidae there are several species that have probably arrived at the same solution independently. Of the 17 species in the family: six form typical leks, namely *Centrocercus*, *Tympanuchus* and the two black grouse; five species, namely the three *Lagopus* and Severtsov's and the Hazel Grouse, are essentially monogamous; and the other six, comprising *Falci pennis*, the Ruffed Grouse, the Blue Grouse and

the two capercaillies, can, to a certain extent, be considered intermediate.

The three species of *Lagopus* are typically monogamous, with males strongly territorial. The White-tailed Ptarmigan establishes territories in the spring, but the other two start as early on as autumn. As well as violent attacks, males manifest their presence using different visual and vocal signals. The Rock Ptarmigan, for example, combines both types of signals in the course of eye-catching advertisement flights. The birds first take off vertically until they are some metres off the ground, sometimes ten or more, then glide with the wings and tail wide open, at the same time making a rhythmical call that is audible up to a kilometre away; finally, they drop down again, still calling, to end up with a display posture. Territories are guarded with greater or lesser tenacity right through the winter until spring, when the females arrive after dissolving their winter flocks. Although there are frequent cases of polygyny, in general each male is paired with a single female, keeping her under surveillance until the end of the incubation period. In the Willow Grouse, an exception in the Tetraonidae, the male even accompanies and protects the offspring.

Hazel Grouse, also monogamous, establish territories and pairs in autumn before the leaves fall, the males using sharp territorial songs, more reminiscent of passerines than of gallinaceous birds; these are answered by the females with similar, though briefer, calls. The pair-bond can weaken during winter, but males remain faithful to their territories. Possession is reaffirmed, on the arrival of spring, by means of short flights between trees, or "flutter-jumps" in which the wings produce a very distinctive whirring sound that can be heard at a distance of 100 m. The famous territorial drumming of the Ruffed Grouse seems to have a similar origin, with males adopting a stiff posture on a fallen tree trunk or some other prominent site and beating their wings. However, while in the Hazel Grouse pairs remain together in spring, at least until incubation begins, male Ruffed Grouse are only concerned about their song posts and may copulate with more females if the opportunity arises; the females, for their part, make their nests without paying any attention at all to the territorial distribution of the males.

The Ruffed Grouse, then, uses a polygynous or, more precisely, promiscuous mating system, in which males maintain large territories and therefore are regularly scattered throughout the forest. The case of the Blue Grouse and the two species of *Falcipectnis* is very similar, with males, clearly polygamous, possessing very large territories within which they display and call. For example, the Blue Grouse has a "hooting" song of half a dozen low notes produced by means of expansions of the oesophagus, and birds will also jump as much as a metre up into the air with loud wingbeats, or "flutter-flights". Capercaillies use a peculiar intermediate system, by which males maintain sizeable territories, but for displaying tend to situate themselves near the points where several territories meet, so as to form a sort of loosely defined arena. These capercaillie display grounds are very variable in size, and also in the number of males in attendance; in Russia, for example, records range from 3-4 males in less than 10 ha, to 20-25 in 100 ha.

True leks have nothing to do with feeding grounds. They are places where year after year males gather together in order to perform their displays. They are typically sited in clearings in forest edge species, such as the black grouse and Sharp-tailed Grouse, and on hillocks with short grass and good visibility in grassland species. Each male maintains only a small display territory, sometimes the same one for several years in succession. The number of males that congregate is also variable, but there are often large numbers, with an average of 6-12 males and a maximum of 26 in the Eurasian Black Grouse, and an average of 8-9 males in the Greater Prairie-chicken, but up to 70 on occasions. In the Sage Grouse numbers vary locally, but in Wyoming there are 70 males on average, and no less than 300 have been cited together.

Males normally arrive at the arenas before dawn and remain there for a few hours each day. Each defends a small territory, the more central the territory, the smaller it is; it can comprise some 500 m² on average in the Greater Prairie-chicken, but, in

marked contrast, it can have a radius of scarcely a metre and a half in the Sage Grouse. More important than the size of the territory is its comparative location, as it is the centre of an arena that the females apparently tend to approach first. The displays in these species can be extraordinarily dramatic and complex. For example, a male prairie-chicken: lowers its head; inflates the combs over its eyes; raises its pinnae, the feathers on the sides of the neck; drops its wings until they touch the ground; lifts its tail and shakes it, or opens and closes it abruptly; drums the ground violently with its feet, in "foot-stamping"; runs alongside other males; puffs out its brightly coloured oesophagic air-sacs; and from time to time makes far-carrying, low intensity booming sounds. Moreover, when the females approach, it jumps into the air, calling and fluttering vigorously, or "flutter-jumping". Of course, there are all kinds of aggressive encounters, some of which are ritualized, but others that are so real that they can end up causing deaths. The jumps, dances and demonstration flights of the Eurasian Black Grouse, and the complex and fascinating "strutting displays" of the Sage Grouse provide equally attractive examples.

Much has been written regarding the possible evolution of these types of display, but they are still far from being well understood. Nevertheless, there are a few things that do seem to be clear. In the first place, there are no leks in cases where the breeding success, either of the male or of the female, clearly depends on the strict defence of a feeding territory. This territory can be crucial before laying, when the food supply is usually more limited, as it must permit the formation of the requisite number of eggs as early as possible (see Food and Feeding). In this situation, typical for example in *Lagopus*, competition between males is essential, and although some females prefer to associate with males that, although already mated, possess very good territories, monogamy is usually the rule. In polygamous species, on the other hand, females build their nests and look after their chicks, without concerning themselves about any form of border. Sometimes two or more nests can be very near one another, for example in the Western Capercaillie, with up to five active nests in little more than a square kilometre.

In second place, it also seems clear that when the female selects males and not territories, she does so basing herself on visual factors, notably the splendour and condition of their plumage, the vigour of their song and display, and finally their performance in direct confrontations in the arena, and the hierarchy that emerges. What is not clear, the "lek paradox", is the reproductive benefit for the female of selecting a good mate, if, in any case, she is not going to receive any help from him in raising the chicks. Be that as it may, sexual selection not only takes place through this behaviour, but is actually very strong; the low proportion of males per lek that manage to mate gives an idea of how strong it is. In the Greater Prairie-chicken, for example, it has been calculated that 71-89% of the copulation in any one arena is carried out by only one or two males, and in the Sage Grouse more than 90% of the copulations are performed by about 10% of the males, the so-called "master cocks". Given additionally the short average lifespan of these birds, it is not surprising that there is such notable dimorphism in size, colour and other secondary sexual characteristics among the polygynous species, whereas such differences are minimal in monogamous species. This exaggerated sexual selection may perhaps also explain the frequency with which abnormally aggressive males appear, like the famous "crazy cock" capercaillies, that without hesitation will attack people, horses, or vehicles that trespass through their leks.

The song or display activity of male grouse has its risks, especially because it can attract the attention of predators. For this reason, it usually takes place during the twilight periods, above all at dawn. Also, males normally select particularly safe places, for example in forest species like the Spruce Grouse or the Ruffed Grouse, areas of rather young forest where the high density of trees may prevent goshawks and other predators from gaining easy access to the site. Display also involves high expenditure of energy, above all among species like the Sage Grouse that form leks.

Territorial defence encounters between rival males of the Western Capercaillie normally begin with ritualized confrontations, both birds adopting a crouching posture and tilting the fully spread tail towards the opponent. At first the birds make powerful belch-like calls and bowing movements, and each pecks out at its opponent's head without actually making contact. If the confrontation continues, it may well turn into a real fight: the pecks intensify and begin to strike home; if one of the birds manages to lay hold of the other's "beard" or its neck, it will immediately attack it with very forceful beats of its wings. It is very unusual for a bird to be killed in the course of one of these combats, but there are various documented cases of males dying shortly afterwards of injuries received.

The date of commencing breeding activity in spring is usually quite variable in each species between different regions, depending on latitude and altitude, and from one year to the next, depending on how soon spring arrives. The Spruce Grouse, for example, begins to lay when roughly 50% of the ground is free of snow. Very probably this is connected with the females' need to have access to food on the ground before they become physiologically capable of forming eggs. On the other hand, laying is relatively synchronous within the same year between pairs in the same zone; for instance, 67% of the Spruce Grouse in one area may begin laying over a period of only 10 days.

The female selects the nest-site, a decision of major importance in terms of eventual breeding fitness. The nest is almost always situated on the ground, although the Western Capercaillie and the Hazel Grouse have been seen using old nests, some metres above ground level, that had been abandoned by other birds, for example birds of prey. Normally the nest is quite well hidden, partially covered by undergrowth in species of open areas, and close to tree trunks or large stones in forest species; at the same time, the incubating bird usually has reasonable visibility. The nest is invariably a shallow bowl, either in a natural depression or in one dug out by the female. Average maximum width varies from about 15 cm in the Hazel Grouse to 25 cm in the Western Capercaillie. The lining is usually rather basic, consisting of blades of grass, dry leaves or twigs that the female picks up whilst in the nest or from a very short radius round about. Often there are also feathers, which are probably deposited accidentally.

Average clutch size ranges from 6 eggs in the Spruce Grouse, the Blue Grouse and the White-tailed Ptarmigan to 12 eggs in the Greater and Lesser Prairie-chickens, with most species laying 8-10 eggs. Although it is difficult to generalize, larger clutches tend to correspond on the one hand to the smaller species, and on the other to the grassland species. A certain correlation with latitude has also been noted, but with the smallest clutches in the more northern species, the opposite of what normally happens in birds. Clutch size is, however, quite variable, both geographically and between years. For example, in

the Blue Grouse, the populations of Vancouver average 6.3 eggs, those of Washington 6.9 and those of Montana 7.5, while the range of averages for the Willow Grouse in Norway varied from 7.8 to 11.2 eggs between 1960 and 1969.

Average egg size ranges from 40 mm x 29 mm in the Hazel Grouse to 57 mm x 42 mm in the Western Capercaillie, with respective average weights of about 20 g and 50 g. As is logical, eggs are larger in the larger species. Nevertheless, in terms of relative proportions the situation is reversed, for instance each egg constitutes 4.5% of the females' body mass in the Hazel Grouse, but only 2.7% in the capercaillies, while the total weight of a typical clutch would be equal to 43% and 20% of the respective female body weights. The shape of the eggs lies somewhere between oval and short subelliptical, and the shell is smooth. The colour is variable, but normally with a creamy buff or yellowish background that is slightly more reddish in *Lagopus* and greenish in the prairie-chickens and the Sage Grouse, probably because of their particular habitats; there are brown or blackish markings, relatively few in most species, but abundant in *Lagopus*.

Incubation does not normally start until the last egg has been laid, and in all species it is undertaken by the female alone. It lasts from 21 days in *Lagopus* to 26 days in the Sage Grouse, averaging longer in the larger species. During this time, females rarely leave the nest more than two or three times a day, preferring to do so early in the morning and late in the evening, for short periods of around twenty minutes or half an hour each time, just enough time to eat. They also take the opportunity to leave their droppings some distance from the nest; these droppings are different from normal ones, as a result of the accumulation of the intestinal faeces that are normally expelled continuously (see General Habits). These droppings, known as "clocker droppings", are easily recognized by their length, their somewhat spiral form and the higher proportion of uric acid.

The incubating female's almost perfect immobility is essential in order to make the most of her cryptic coloration. In this she trusts blindly, so much so that sometimes an incubating bird will allow itself to be touched. Nevertheless, animals such as foxes, badgers, wild boars, squirrels or different corvids

often find the nests, and predation is, in fact, responsible for the vast majority of losses that occur. According to the extensive literature available, some or all of the eggs usually manage to hatch at around 60-70% of all nests. The genus *Lagopus* is exceptional in generally having a success rate of over 80%, while the grassland species hardly reach 40-50%.

In cases of complete clutch loss, females can in principle, after a couple of weeks, lay a replacement clutch, normally smaller than the initial one, in another nest. However, this seems to be comparatively rare in most species, although it may simply be due to the scarcity of information available. The prairie-chickens are the exception, perhaps as an adaptation to the high losses that they suffer like many grassland birds. A study of the Greater Prairie-chicken showed that, of 14 females equipped with transmitters, three nested again after losing the first clutch, one of them twice; and another study has even shown that third attempts are actually common in the Sharp-tailed Grouse.

Hatching is almost simultaneous at any particular nest, due mainly to the communication that is established through individual chicks cheeping at different rhythms which indicate that they are closer to, or further from, hatching. From the beginning of the pipping of the first egg until the last chick hatches takes barely a day, or at most two. Very shortly afterwards, as soon as all the chicks have dried out, they abandon the nest following the female. Like other galliform chicks, they are extremely precocial. The digestive tract and the legs develop particularly quickly, so that the chicks can immediately eat on their own, without the female having to show them what to eat or how to eat it, and they may travel several hundred metres per day. Their wings also develop extremely early: at hatching, most, if not all, of the primaries can already be seen in active growth, as can some secondaries and the greater upperwing-coverts. In very few days, perhaps only 4-5 in the Hazel Grouse, they are capable of raising themselves several centimetres off the ground, and in about 10 days they can fly up several metres. These precocial flights offer them some security against predators, and, for instance, from an early stage they can already spend the night in branches some way off the ground.

Again as in many other Galliformes, females look after their chicks extraordinarily well. Besides leading them to areas that are rich in the food they need, basically insects during the first few days, they defend them fearlessly, often attacking even humans. They also resort to distraction displays, such as feigning injury. The alarm calls of the mother cause the brood to disperse, each chick running in a different direction to hide and remain still until the danger passes. But perhaps most importantly, the female protects the chicks from the adversities of the climate. In the habitats occupied by grouse, sudden cold, rain and sometimes snow can appear unexpectedly very late in the season, and, as the chicks are not capable of efficient thermoregulation for quite some time, it is essential for the mother to warm them by covering them with her wings. It is claimed that, after five minutes of walking alone in a fairly moderate temperature of 12°C, small capercaillie chicks start to search for some source of heat, and if they do not find it, they die within three quarters of an hour. As soon as the chicks are able to do without brooding, it becomes rare: in the Blue Grouse, almost 90% of the observations of females brooding chicks take place in the first week after hatching. Nevertheless, chick mortality due to inclement weather is almost always high in the Tetraonidae.

The growth of the chicks is relatively rapid. Long before they have reached adult size and weight, they go through their first moult, beginning with the innermost primary, which is shed at two weeks in the Ruffed Grouse and at four in the Greater Prairie-chicken. Little by little the chicks wander farther from their mother when foraging, and towards the end of summer or the beginning of autumn, when they are about three months old, the family bonds are finally broken and each chick goes off on its own. By this time predators or bad weather have reduced the size of the brood significantly. In one study of the Western Capercaillie in Germany, for example, of 8-9 chicks leaving the nest on average, only 3-4 survived after a couple of months. In another study of the Sage Grouse in Colorado,

families contained an average of 5-6 chicks in June, but only 2-3 by August. Comparable figures are available for other species, although logically they are lower on average in those that lay fewer eggs initially, like the Blue Grouse, than in those that lay more, above all *Tympanuchus*. In fact, the Greater Prairie-chicken can have an average of 6-6 chicks per family well into the summer. Very often there are significant variations from one year to the next within the same species and the same region. For instance, in Scotland in the period 1945-1963, the Rock Ptarmigan raised average broods of 1-2 to 6-2 chicks.

By linking hatching success with average brood size, it is possible to make rough estimates regarding the levels of recruitment that probably operate in grouse populations. Another factor to remember is that grouse reach sexual maturity in their first year, although males of polygynous species, especially those that compete at leks, do not manage to copulate until at least their second year. All things considered, annual recruitment is fairly high in comparison to that of other birds. A logical deduction from this, however, is that the average lifespan of grouse should be very short. Indeed, annual adult survival rates that have been calculated for different species are usually between a maximum of 60-65% for the Blue Grouse and the Western Capercaillie, and around 30% in the Hazel and Willow Grouse. These figures give respective average lifespans of two years or a little more in the first case, and barely 10 months in the second, in both cases starting from the first autumn. Thus a generalization for a medium-sized member of Tetraonidae would give adult mortality of about 50%, with the corresponding further year and a half of life for those young birds that succeed in surviving the summer.

As is to be expected, clutch size corresponds closely to the typical mortality rate of each species, so that larger species generally live longer than smaller ones, and forest species live longer than those of open country. An interesting case is that of the White-tailed Ptarmigan, which differs notably from its congeners with their relatively small clutches of 5-6 eggs on average, and their high life expectancy of about three years. This could perhaps be due to the relatively low density of predators in the high mountains in comparison with the Arctic tundra, where there are many animals that habitually prey on the other *Lagopus* species, notably the Arctic fox (*Alopex lagopus*), the stoat (*Mustela erminea*), the Gyrfalcon (*Falco rusticolus*) and the Snowy Owl (*Nyctea scandiaca*). As is to be expected for primary consumers, grouse are not by any means short of enemies, and predation is the main cause of mortality; few grouse can meet a peaceful end! A wide diversity of carnivorous mammals (*Martes*, *Lynx*, *Vulpes*, *Urocyon*, *Canis*), raptors (*Accipiter*, *Buteo*, *Aquila*, *Falco*) and owls (*Strix*, *Bubo*) can be considered important predators, as shown by several studies. The Northern Goshawk seems to be a true specialist predator of forest grouse, accounting for 74% of the recorded captures of Blue Grouse in a study in British Columbia; it is also the most important predator of the Hazel Grouse in Eurasia, and of the Ruffed Grouse in America. A single nesting pair of goshawks has been calculated to kill up to 40 Hazel Grouse a year in the Polish forest of Bialowieza, and up to about 300 Ruffed Grouse on Cloquet Island, Minnesota (USA). Logically, due to the differences in leaf duration, those species that spend the winter in conifer forests are better protected than those that winter in deciduous ones, which helps to explain why mortality is lower in the Spruce and Blue Grouse and the capercaillies.

Of course, in addition to predators, disease and parasites also take their toll. In the Red Grouse, for example, the intestinal nematode *Trychostrongylus tenuis* has been identified as an important cause of mortality, especially of chicks. Given that the incidence of this parasitic worm is more pronounced when population densities are at their highest, it has even been imputed as the cause of population cycles. Up to 20 different species of nematode are known to infect the Ruffed Grouse. The performance of males at the lek can be affected by a serious infestation, and recently this has even been proposed as a possible explanation for the "lek paradox". What the females obtain upon selecting males with better developed secondary

The nest of the Ruffed Grouse is a bowl formed in leaves on the forest floor. It is often protected, at least on one side, by boulders or by some other upright object, such as a stump, a log or the base of a tree. Nevertheless, whilst the female is incubating, her best protection against predators is the cryptic coloration and pattern of her plumage. Hen grouse are so confident in their ability to pass unseen on the nest that it is sometimes possible actually to touch an incubating bird before she decides to leave the nest.

[*Bonasa umbellus*.

FLPA]

sexual features, such as plumage in excellent condition, cervical sacs without haematomas due to lice, a high frequency of strutting, and so on, would be those genes resistant to parasites for their immediate descendants. A larger number would survive and this would obviously increase the individual fitness of the female that has made the appropriate selection.

A characteristic of animals, like the Tetraonidae, that have high birth and death rates, is that their population levels are usually very unstable, and this certainly is the case of the grouse. For example, extreme densities of 0.5-2.9 birds/10 hectares have been registered for the Spruce Grouse in Alberta (Canada) over a period of 21 years, in other words almost six times as many birds some years as in others. Similar or even greater variations have been recorded for the Willow Grouse and the Rock Ptarmigan in different regions. However, the most interesting feature is that these population changes usually follow more or less regular cycles that can sometimes be detected with only an elementary analysis of the hunting statistics. A cycle of roughly ten years for the Ruffed Grouse in North America and other boreal animals, such as the Canadian lynx (*Lynx canadensis*) and the snowshoe hare (*Lepus americanus*), has been well known for many years. Cycles of ten years have also been noted in the Rock Ptarmigan in Alaska and Greenland, but in the same species in Iceland cycles are of 3-4 years. Similarly, the Red Grouse has cycles of six years in Scotland, and of 3-4 years in Fennoscandia and northern Russia. Similar cycles have been documented for the Western and Black-billed Capercaillies, the Eurasian Black Grouse and the Hazel Grouse.

The phenomenon has intrigued animal ecologists, and many theories have been advanced to explain it. Two kinds of possible population regulating factors have been postulated, extrinsic and intrinsic. Within the first are changes in predator density, the incidence of parasites and disease, food quality or climate, but none of these factors has offered a convincing explanation, particularly considering the surprising regularity of the cycles. The intrinsic alternatives are connected with the typical behaviour of individuals. Basically, during periods of high population density male territoriality is intensified, so that in autumn males defend larger areas, expelling the weaker or less aggressive individuals, causing higher mortality of such birds during the winter. This has a genetic implication, since in these periods the more aggressive phenotypes with a higher possibility of survival would be selected. Gradually the accu-

mulation of aggressive phenotypes in the population would cause average territory size to grow, and at the same time the number of individuals to decrease. Inversely, periods of low density would catalyse the selection of tolerant phenotypes, perhaps because very aggressive males consume too much energy in defending their extensive territories or are more exposed to predation, and in the long run this different type of selection would allow the demographic levels to rise again.

In spite of the definite appeal of this proposal, made originally by D. Chitty in 1967, and applicable to other vertebrates with fluctuating populations, such as voles or lemmings, many authors feel that this is still far from being a fully satisfactory explanation. At present this hypothesis is the subject of considerable experimental research, which may soon offer convincing proof. It has already been seen, for example, that chicks in captivity corresponding to different population levels show very clear differences in the frequency and intensity of their antagonistic behaviour, and that these differences are inheritable.

Movements

Grouse tend not to be very mobile, either in their daily routine or throughout the year. This is only to be expected from their morphology, which is not well adapted to sustained flight, or from their ecology, which is based on a relatively easily obtained vegetarian diet. They do not migrate in the strict sense. In some species, certain populations move within a range of dozens, or at most hundreds of kilometres, but these movements generally lack clear direction or precise timing, and are often determined by local weather conditions or food availability. Their movements can thus be better described as nomadic or even erratic.

The forest species are usually the least mobile, probably because their winter food always remains above the snow. However, definite food preferences lead to some local displacements. Most of the Western Capercaillies that nest in broad-leaved forests in the southern Urals spend the winter in pine forests fairly far away, while in the Blue Grouse a reverse altitudinal movement occurs, birds tending to winter in conifer forests high up the mountains. The genera *Falcipectnis*, *Dendragapus*, *Tetrao* and especially *Bonasa* are strongly sedentary. In the Hazel Grouse, for example, a study of ringed birds in Russia showed

During the breeding season, the Rock Ptarmigan prefers areas with more or less continuous heather, broken by outcrops or large boulders. The nest is simply a shallow depression produced by the female's weight and movements, although the bottom may be lined with some feathers or leaves. It is normally situated beside a bush or a large rock which gives the female some extra cover during the 21-24 days of incubation. Nonetheless, as in other grouse species, the female relies mainly on her remarkably cryptic plumage to escape the attentions of predators.

[*Lagopus muta millaisi*, Cairngorm National Nature Reserve, Scotland. Photo: Benoît Renevey]

that more than half the birds recovered were found within a radius of 200 m from the point of ringing, with 88% of them less than 500 m away, while the farthest was only 1500 m away.

At the opposite extreme are the genus *Lagopus* and the Sage Grouse, which may perhaps be qualified as partial migrants. In the Sage Grouse, a fair number of high altitude breeding areas are completely abandoned during winter, in favour of quite distant valleys, sometimes up to 100 or 150 km away. In the Willow Grouse, and to a lesser extent in the Rock Ptarmigan, different populations carry out altitudinal movements over short distances. Some populations of the Arctic tundra, in Siberia or Canada, regularly move towards forested regions quite some way farther south. Thus, it is calculated that roughly 50,000 Willow Grouse pass every autumn through the Anaktuvuk Pass, in the Brooks Range of northern Alaska. Those that nest on the Russian islands of Kolguev and New Siberia move to the mainland, covering distances of 80 km and 120 km respectively, although perhaps only when the straits have enough ice on which they can rest if need be. Some years there are mass movements, for example of the Rock Ptarmigan in Greenland; as with other Arctic species, like lemmings, such movements could be related to exceptionally high population levels. On such occasions the Greenland ptarmigans suddenly erupt in large flocks in the south of the island, after having travelled hundreds of kilometres, and it is believed that some may even continue further, as some birds have been found in Iceland with non-volcanic grit in their gizzards. It is clear that occasional irruptive movements may also occur in forest species, and, for example, in the autumns of 1943 and 1944 in Sweden long range movements of Western Capercaillies and Eurasian Black Grouse were registered, with some birds recovered at more than a thousand kilometres away. Movements like this may also occur fairly frequently in Siberia.

Nevertheless, there are two apparently more or less fixed rules in this family, as in so many other bird families. One is the autumn dispersal of juveniles, and the other that males tend to be more tied to their habitual areas than females, so that, if they do actually leave, they move shorter distances on average and for shorter periods. Therefore, in ringing studies there is often a very clear split between the sexes and also different age categories. For example, in the White-tailed Ptarmigan in Colorado, while adult males make average movements of only 2.5

km and subadult males of 4.0 km, the corresponding figures for adult and subadult females are 6.8 km and 8.5 km.

Relationship with Man

Man's main interest in the Tetraonidae over the years stems from hunting, and it is naturally much more highly developed than any other relationship between the two. Prolific and common over extensive areas, of good size and flavour, they have always been prized as a good source of protein by diverse northern cultures, and they are perhaps only surpassed by the Anatidae in this respect. Grouse bones are regularly found in European Paleolithic middens, showing that the climate was actually colder then than at present. The flesh of these birds is still important for many peoples of the North, from the Lapps to the Eskimos. Curiously, man has not domesticated any species, although there are several that can be kept and raised perfectly well in captivity.

The statistics available for the hunting of grouse at a global level are rather incomplete. For the American species, P. A. Johnsgard calculated that at the end of the 1970's almost 8,500,000 Tetraonidae were killed annually, 5,000,000 of them in the USA. The most intensively hunted species, with some 6,000,000 birds killed per year, was the Ruffed Grouse, followed at considerable distance by the Sharp-tailed Grouse with 700,000, the Spruce Grouse with 550,000, the Blue Grouse with 520,000, the genus *Lagopus* with 300,000, and the Sage Grouse with 270,000. The figures corresponding to the now rare prairie-chickens were a good deal lower, with 61,000 Greater and 6700 Lesser Prairie-chickens killed.

In the same way that the Ruffed Grouse is an extremely popular game bird in North America, so is its relative the Hazel Grouse in Russia, especially in Siberia, although it is less so in Western Europe. In the Old World, the most hunted species is the Willow Grouse, especially in the former Soviet Union, where annual captures have been calculated in the order of about 8,000,000 birds. The same species is also intensively hunted in the British Isles, where the local race is the Red Grouse. The number of birds shot some years in Scotland and northern England is quite remarkable, with up to about 2,500,000 birds in 1911. But since the 1940's there has been a

gradual decline in numbers, which were down to under 500,000 pairs around 1976, and, in spite of a comparative recovery recently, still no more than 400,000 birds a year are being shot. Given the economic importance of shooting, it is not surprising that a great deal of research has been carried out, and this has certainly resulted in the species' biology being much better known. It now seems that the decline in numbers is not due to excessive hunting but rather to inadequate management of the habitat, perhaps because fewer gamekeepers and shepherds are now employed. Some areas are overgrazed, while in others the heather is allowed to grow large and old, whereas before it underwent careful rotational burning in order to guarantee both enough ground cover and the continuous provision of nutritious stalks, with the result that now it can not offer the same sustenance to the grouse. Additional factors are the exponential increase of predators, with an estimated thirtyfold increase in the number of foxes between 1920 and 1970, and in some areas the fragmentation of suitable habitat, so that the species is progressively reduced to pockets of such habitat, where, in the case of extinction, recolonization becomes increasingly unlikely. Even so, in Britain there are still around 1,000,000 ha in which hunting of the Red Grouse contributes to the maintenance of the moors with their characteristic flora and fauna; many of these moors might otherwise be destined to other uses that are far from attractive from the point of view of conservation, such as conifer plantations.

In the rest of Western Europe, grouse are generally so scarce nowadays that they have little importance as gamebirds, except in Finland, Scandinavia and the Alpine countries. The Western Capercaillie is already strictly protected almost throughout Central Europe, for example since 1970 in Germany. The Eurasian Black Grouse is hunted only in limited numbers, around 1500 males a year in the cases of Austria, Switzerland and Poland, while the number of Hazel Grouse taken tends to be even smaller. On the other hand, up to end of the 1970's in Norway and Sweden taken together, some 40,000 Black Grouse, 30,000 Western Capercaillies and 30,000 Hazel Grouse were still shot. In Finland, annual figures

throughout the 1960's and 1970's were even higher, with 54,500-171,500 Eurasian Black Grouse, 14,500-33,000 Western Capercaillie and 28,200-69,600 Hazel Grouse. In these nordic countries, quite a number of Willow Grouse and Rock Ptarmigans are also hunted, especially in Norway, where the annual average for the period 1975-1980 was 423,000 birds killed.

Nevertheless, the figures often do not reflect the full economic and social importance of grouse hunting. Some species are considered highly desirable trophies, mainly due to their size and striking appearance. Of some interest are the peculiar hunting practices used for species with courtship displays. The Western Capercaillie and the Eurasian Black Grouse have been hunted traditionally in spring in Central Europe, although it is only males that may be taken. In the case of the former, hunters have to approach the displaying males stealthily before dawn, taking advantage of moments of deafness that the birds seem to experience during certain phases of their song.

Status and Conservation

Although nowadays only one species in this family is considered globally threatened, there are quite a few that have shown special sensitivity to alterations of their habitat due to man. In particular, marked decreases in numbers and considerable reductions in range have taken place on two main fronts, the forests of Europe and the grasslands of North America. But the typically huge ranges of the Tetraonidae, extending far into cold and sparsely populated regions of Siberia and Canada, mean that the various different species can generally be considered relatively secure.

The exceptions may be the three species with restricted ranges, the Caucasian Black Grouse, the Siberian Grouse and Severtsov's Grouse. The first of these is the only species in the family that is currently considered to be globally threatened. It is classified as Insufficiently Known, which reflects a rather generalized uncertainty about its status. In Azerbaijan, it is

The eggs of the Eurasian Black Grouse are creamy white in background colour, with profuse brown speckles. In this species, clutch size ranges from six to eleven eggs, apparently with a higher average number of eggs in areas where the population density is higher. The nest is a scrape in the ground lined with plant material and feathers, and is normally well hidden amongst shrubs or tall vegetation. During the four-week incubation period the female normally leaves the nest to feed three times a day, in the morning, the early afternoon and the evening.

As a consequence of the cold climates inhabited by grouse, and the chicks' insufficient capacity for thermoregulation in their first days of life, brooding is one of the most important functions performed by the female towards the survival of her chicks. While they are young, it is very common for the female to keep them warm by covering them with her wings, as illustrated by this Willow Grouse. This is particularly important during cold spells, rain or even snow, which can arrive quite unexpectedly at any time of year in many parts of the family's range.

[*Lagopus lagopus*.

Krasemann/
NHPA]

uncommon, with perhaps some 1500-2000 individuals; here, outside protected areas it has decreased as a result of intensive grazing of subalpine meadows, and also a certain amount of predation of young by sheepdogs. However, it may still be reasonably common elsewhere. The Siberian Grouse is a rare bird everywhere, and it tends to disappear quickly from the areas of the taiga settled by man, perhaps because its particularly unwary behaviour makes it excessively vulnerable to hunting; in some places it can apparently be captured with long, hooked poles. There is virtually no information available on the population sizes and trends of Severtsov's Grouse, and its numbers could be very small.

At the subspecies level there are more forms that cause concern, especially in the genus *Lagopus*, with quite a few isolated populations, often with limited numbers in southern areas. Some are suffering from problems caused by human recreational activities, such as ski-ing, and also from too intensive hunting pressure. On top of this are possible difficulties arising from climatic variations, impoverished food supplies and other limitations. Nevertheless, at the species level, because of the remote, unproductive areas they occupy, there is no doubt that these three forms have a fairly optimistic perspective for the future.

Although most species are subjected to exploitation as gamebirds (see Relationship with Man), it seems that this has rarely had an excessively negative impact as regards the conservation of the species. The high birth and death rates of these birds mean that hunting yields are normally well below the sustainable maximum. Much of the mortality caused by a limited degree of hunting should be offset by the increased possibility of survival for each individual that is not killed. This is especially true over the winter, as there will be reduced competition for resources, and maybe also a decrease in the incidence of predation, parasites and other mortality factors that are density dependent. To what point this compensation is partial or even total is still not very clear, but, for example, it is known that a harvest rate of 30% in the Red Grouse can be sustained with no drop in numbers at all. On the other hand, the same high demographic rates allow rapid recoveries in protected areas, or during specially extended close seasons. In principle, introductions or reintroductions also tend to give

good results, due in part to the fact that grouse, like most Galliformes, breed well in captivity.

On the whole, the American grassland species are those that have suffered most from the actions of man. The arrival of agriculture had a major impact on the prairie-chickens, and a lesser one on the Sharp-tailed Grouse, which is more a species of the ecotone. The story of the nominate race of the Greater Prairie-chicken, the "Heath Hen" of the east coast colonists, is well known. Originally, it seems that it was commonly found from Massachusetts to Maryland. One of the first laws to protect any bird species in America was decreed in New York, as early as 1791, establishing a spring ban on the massive captures of this species that took place on Long Island, for sale in markets. But around 1844 the species disappeared from the state of New York, and by about 1869 it had gone from the rest of its range except the island of Martha's Vineyard in southern Massachusetts. There, protected by law from 1824, the species underwent considerable population cycles, for example with only 60 birds in 1908, as opposed to 2000 in 1916. In spite of all the efforts made, the last representative, a ringed male, which was apparently the lone survivor during almost five of its eight years of life, was seen for last time in March 1932. Another race, *attwateri* or Attwater's Prairie-chicken, restricted to the coast of Texas, was classified as Rare in the 1978/1979 Red Data Book. At present, its total population is down to under 1000 birds, a far cry from the 1,000,000 that are reckoned to have occurred during the last century. The transformation of the habitat into agricultural land, mainly rice fields, seems to have been the main cause of this decline.

The most widespread race of the species, *pinnatus*, actually benefited at first with the arrival of agriculture in the prairies, due to the importance of grain as a winter food source. In spite of the large-scale hunting it was subjected to, around the end of last century not only did it reach maximum populations in many areas, but it also spread fairly rapidly to states to the west and north, as well as to the prairie provinces of Canada, where it reached the level of Edmonton, Alberta, in 1900. Later, however, the increasing intensification of agriculture reversed the trend, as the virgin stretches of prairie that the bird required for breeding habitat disappeared. Virtually eradicated from Canada, it is now thought to be rare or regionally extinct in the

states of Michigan, Ohio, Kentucky, Indiana, Illinois and Iowa, and in the south, in Arkansas and Texas, in other words most of its original range in what was the Tall-grass Prairie. Curiously, it is in the western states of Short-grass Prairie, like Kansas and Nebraska, where the species was more marginal, that the healthiest populations are now to be found. This is undoubtedly because of the pastoral, rather than agricultural, use of the land, whereas in Missouri, for example, it is believed that no more than 0.5% of the original prairie remains.

The status of the Lesser Prairie-chicken is reckoned to be stable. However, its total population may number only some 50,000 birds, while it has a rather limited range of about 25,000 km² in only four states, less than 10% of its original range, so there is cause for concern. The prairie-chickens have been, and probably still are, the main "flagship species" in the fight for the conservation of what remains of the prairies. They have, for example, been the motivation behind the creation of numerous reserves, which, if these are large enough to cater for the needs of these species, are also sufficient for all the other prairie birds. By 1964, within the National Grassland System, the Federal Government of the USA already had 19 nature reserves in 11 different states, covering a total of 1,600,000 ha, while there were many other reserves both publicly owned and belonging to private conservation organizations. Other conservation measures already under way, with better or worse results, include: provision of extra food; elimination of introduced pheasants; predator control; reintroduction, or bolstering of populations; and, most importantly, habitat management and improvement, through the regulation of grazing by sheep, and also periodical controlled burning. Such burning is essential, as the invasion of the grasslands by shrubby vegetation, either autochthonous or introduced, is a threat that could become particularly serious in the long term.

Up to now, the Sage Grouse has been slightly more secure in its habitat in the arid western plains. But agriculture is being steadily intensified in this area, supported by modern irrigation techniques which combine very deep wells and centre-pivot systems. In addition, the sagebrush that is so important to the species is increasingly being eliminated, either mechanically or by herbicide spraying, with a view to improving the land for cattle ranching. Indeed, by 1967 some 12,000-15,000 km² of sagebrush had already been removed, while by 1975 the original expanse of sagebrush in Montana had been reduced to a mere 10%.

In the case of the forest species, moderate levels of logging generally have a beneficial effect on populations, as often does fire, at least temporarily, revitalizing the forest by allowing the growth of patches of broad-leaved trees, such as birches or aspens, or leaving glades open for colonization by berry-bearing shrubs, such as *Vaccinium*, and therefore increasing the food

supply. Because of this colonization by man of the boreal forest zone, different grouse species have been able to increase their density and range temporarily. For example, the numbers of Eurasian Black Grouse are said to have increased in many parts of Europe during the last century, and they are apparently still increasing in much of Siberia. However, intensive exploitation of forests ends up eliminating marginal areas, for example the planting of pines on heather moors or in birch forests, while it also converts the forests into monotonous expanses of trees all of the same age. In such circumstances, the habitat is substantially altered, especially as regards food potential, and the grouse populations very quickly go into decline. The Eurasian Black Grouse has now been converted into an authentic rarity in Central Europe, eliminated not only from the plains but also from mountains such as the Vosges, the Jura and the Sudety, and recent trends in Scandinavia and Finland are little better.

Perhaps the situation is even worse for the Western Capercaillie, a more distinct forest specialist. It was formerly found throughout the cold and temperate forests of Europe, but now, except in Fenno-Scandia and Russia, it is only found in mountains at fairly high altitude, for example in the Alps normally only above 1200 m. In the past, the main reason for the decimation of populations of this magnificent species was forest destruction carried out in order to make way for agriculture and livestock. The later policies for forest development, along with special game protection measures achieved notable recoveries in many areas. For example, in the British Isles the species was eradicated towards the end of the seventeenth century, but it was successfully reintroduced in about 1837-1838, and for some time underwent considerable increases. But now, from Scotland to Finland and from the Cantabrian Mountains to the Carpathians, populations are everywhere in decline, and again forestry, now in its modern industrial style, seems to be the culprit. In Scotland, for example, average winter densities have been recorded three times higher in natural forests than in plantations. Similarly, it has been seen in Scandinavia that modern forestry techniques struggle to satisfy the ecological requirements of the species, both in the breeding season and in winter. The future of the species in Western Europe seems even less certain if other aggravating factors are considered, such as the genetic isolation of the small residual populations, poaching, problems caused by ski-ing and tourism in general, the creation of new paths and roads, pollution in the form of acid rain, and the ensuing destruction of forests, and in southern areas, perhaps, long-term climatic changes.

General Bibliography

- Aldrich (1963), Andreev (1980, 1988a), Aschenbrenner (1982), Baines & Lindén (1991), Bateson (1983), Bendell (1972), Bergerud (1985, 1988b, 1988c, 1988d), Bergerud & Gratson (1988a, 1988b), Bergerud *et al.* (1985), Braun & Willers (1967), Brodtkorb (1964), Bryant & Kuropat (1980), Chitty (1967), Ellison (1991), Gibson & Bradbury (1985), Glutz von Blotzheim *et al.* (1985), Gray (1958), Hamerstrom & Hamerstrom (1960), Hannon (1989), Hjorth (1970, 1976), Höglund, J. (1989), Höglund, N.H. (1964c), Höhn (1977), Holman (1964), Hudson & Lovel (1984), Janossy (1976), Johnsgard (1982, 1983a, 1985), Johnson & Lockner (1968), Jönsson *et al.* (1991), Keith (1963), Kirikov (1975), Klaus (1991), Krebs (1978), Lack (1964), Leopold (1953), Lindén (1989b), Lindén & Rajala (1981), Lovel (1979, 1982), Lovel & Hudson (1985, 1988), Marcstrom (1988), Marcstrom *et al.* (1988), Marjakangas (1980), Marjakangas & Moss (1991), McEwen *et al.* (1969), McGowan (1975b), Morioka (1975), Moss (1983), Moss & Hansen (1980), Moss & Watson (1991a), Moss *et al.* (1974), Myrberger (1985), Oakes (1992), Page & Bergerud (1988), Peterle (1951), Peters (1934), Porkert (1969b, 1972, 1975a, 1975b, 1976, 1979, 1983, 1991a, 1991b), Potapov (1969, 1970, 1972, 1976, 1982a, 1985, 1992a), Raethel (1988), Remington (1989), Robel (1972), Rutgers & Norris (1970), Salomonsen (1972), Semenov-Tjan-Shanskij (1960), Short (1967, 1969), Sibley (1957), Sibley & Ahlquist (1990), Sibley & Monroe (1990), Sibley *et al.* (1988), Siivonen (1957), Stock & Bunch (1982), Stokkan (1992), Stresemann (1966), Sych & Bogdanovich (1988), Thomas (1987), Veghte & Herreid (1965), Verheyen (1956), Volkov (1968), de Vos (1979), Watson & Moss (1979), Wiley (1974), Wittenberger (1978).

The Caucasian Black Grouse is the only species of the family that is currently considered globally threatened. Intensive grazing of subalpine meadows, predation of young birds by sheepdogs and hunting are apparently the causes of the species' decline, and even local extinction, in many parts of its rather restricted range.

PLATE 36

inches 8
cm 20

Genus *FALCIPENNIS* Elliot, 1864

1. Siberian Grouse

Falcipennis falcipennis

French: Tétrás de Sibérie **German:** Sichelhuhn **Spanish:** Gallo Siberiano
Other common names: Sharp-winged Grouse, Siberian/Asian Spruce Grouse

Taxonomy. *Tetrao falcipennis* Hartlaub, 1855, southern shores of Sea of Okhotsk and Stanovoy Mountains.

Closely related to *F. canadensis*, with which forms superspecies; these two often included in *Dendragapus*, but probably merit generic separation (see page 376). Birds from Sakhalin I were described as race *muratai*, but differences are very slight. Monotypic.

Distribution. E Transbaikalia and S Yakutia E to Sea of Okhotsk, and S to Little Chingan Mts, lower Amur region and Sikhote-Alin Mts; Sakhalin I.

Descriptive notes. 38-43 cm; c. 700 g. Mostly rich brown and black; white line around black throat; bill black, combs reddish. Differs from *F. canadensis* in underparts barred black and white; outer primaries narrow and pointed. Female much paler than male, with extensive light spots and streaks above and below, and with strong russet tones, especially on head and neck. First-winter male like adult male, but with brown spots on upperparts and pale ochre shaft streaks; juvenile similar to female.

Habitat. Coniferous forests, mainly of spruce (e.g. *Picea jezoensis*) and fir (*Abies nephrolepis*). Prefers moist, shady areas alternat-

ing with coppices of spruce and larch (*Larix*) and open glades; also favours thick understorey of moss and berries (*Vaccinium*, *Empetrum*, *Rubus*, *Ribes*).

Food and Feeding. Diet based heavily on spruce and fir needles, especially during winter. In summer and autumn, also berries and leaves of *Vaccinium*, *Empetrum*, *Rubus* and other shrubs, as well as some insects. Juveniles feed mostly on insects, changing gradually to berries, and, from late summer, to fir needles.

Breeding. Laying May-Jun. Promiscuous; males dispersed. Nest is depression on ground, with simple lining. Lays 6-10 eggs; incubation period unknown; chicks' down as in *F. canadensis*, mostly buff and brown above, with black-bordered cap.

Movements. Sedentary; seasonally performs limited vertical movements in some mountain areas.

Status and Conservation. Not globally threatened. Included in USSR Red Data Book in 1978, and global status should probably be revised. Has relatively small range and nowhere seems to be common, e.g. densities of 0.25 birds/km² in Slendyi Basin, and 3 pairs/km² in Bikin Range. Disappears rapidly from recently colonized areas, apparently because does not fear man, and is excessively confiding.

Bibliography. Abramov (1962), Cheng Tso-hin (1987), Dementiev & Gladkov (1952), Etchécopar & Hile (1978), Flint *et al.* (1984), Johnsgard (1983a), Judakov (1972), Kirikov (1975), Kirikov & Schubnikova (1968), Kuz'mina (1992), Meyer de Schauensee (1984), Potapov (1985), Potapov & Flint (1989), Pukinskij & Nikanorov (1974), Raethel (1988), Stepanyan (1962), Yamashina (1939).

2. Spruce Grouse

Falcipennis canadensis

French: Tétrás du Canada **German:** Tannenhuhn **Spanish:** Gallo Canadiense
Other common names: Canada Grouse; Franklin's Grouse (*franklinii*)

Taxonomy. *Tetrao canadensis* Linnaeus, 1758, Hudson Bay.

Closely related to *F. falcipennis*, with which forms superspecies; these two often included in *Dendragapus*, but probably merit generic separation (see page 376); present species formerly awarded monotypic genus *Canachites*. Occasional hybrids are known with *Dendragapus obscurus*, *Lagopus lagopus* and *Bonasa umbellus*. Race *osgoodi* often included in nominate. Six subspecies currently recognized.

Subspecies and Distribution.

F. c. osgoodi (Bishop, 1900) - Alaska (Yukon and Kowak Valleys) and NW Canada E to Great Slave L. and L. Athabaska.

F. c. atratus (Grinnell, 1910) - S Alaska (Bristol Bay to Cook Inlet and Prince William Sound).

F. c. canadensis (Linnaeus, 1758) - Canada from C. Alberta to Labrador Peninsula.

F. c. canace (Linnaeus, 1766) - SW Canada (S. Manitoba to New Brunswick and Nova Scotia) and NE USA (N. Minnesota to E. Maine).

F. c. torridus Uttal, 1939 - Nova Scotia.

F. c. franklinii (Douglas, 1829) - SE Alaska and British Columbia through N. Rocky Mts to C. Idaho and NW Wyoming.

Introduced (*canadensis*) to Newfoundland.

Descriptive notes. 38-43 cm; male 550-650 g, female 450-550 g. Dark grouse, mainly grey above and black below, with white spots along sides, and throat bordered with white. Lacks white bars in underparts and attenuated outer primaries of *F. falcipennis*; lacks cervical sacs of *Dendragapus obscurus*. Bill blackish sepia; combs scarlet in both sexes, becoming geranium red in males during courtship. Female paler, extensively barred, with throat and breast tawny to whitish, sides predominantly ochraceous and underparts barred brown and white; two colour morphs, grey and red. First-winter bird like adult, but two outer primaries more pointed than others and buffier. Juvenile resembles adult female, with white or buff markings at tips of wing coverts and remiges. Races differ mainly in extent of white on underparts and on tail pattern.

Habitat. Distribution largely coincides with boreal coniferous forest; linked mainly with pine (*Pinus banksiana*, *P. contorta*), but also spruce (*Picea mariana*, *P. glauca*, *F. rubens*), fir (*Abies balsamea*) and others. Apparently prefers young successional stands: rather dense, 7-14 m in height, with relatively well developed middle storey. Also, at least during summer, rich understorey of blueberries (*Vaccinium*) and other low shrubs. Territorial males select somewhat open stands. More of a generalist in winter.

Food and Feeding. During winter, mainly pine or spruce needles or both, constituting up to 100%. Summer and autumn food of adults is mostly growing tips, leaves, flowers and berries of blueberry, crowberry (*Empetrum nigrum*) and other ground vegetation. Locally, larches, e.g. *Larix laricina*, important in autumn. Chicks under 1 week old subsist entirely on arthropods, but soon change to berries, and in autumn to needles. Fungi may be important for chicks. Forages throughout day, with peaks in early morning and late afternoon.

Breeding. Laying mostly in Jun. Promiscuous;

males dispersed. Nest is simple depression, lined with dead needles or leaves and some feathers, well concealed by overhead cover, usually at base of a pine or spruce. Lays 5-6 eggs (4-7); incubation 23-24 days; downy chicks not unlike those of *Lagopus*, rufous above, with chestnut brown cap bordered with black; already has primaries 1-7 at hatching, first one shed at c. 19 days; chicks flutter up from ground at 1 week. Clutches that hatch, 40-80% in different studies, less in *franklinii*; average brood 3.2-5.5. In first year, most females (71-100%) lay, but only 40-50% of males defend territories. Annual adult survival rates: 32-44% in male, 23-49% in female; in *franklinii*, 75% in male, 63% in female. Three ringed birds at least 13 years old.

Movements. Largely sedentary. In SW Alberta 25% of adults (35% of females, 7% of males) undertake annual movements of up to 11 km between breeding and wintering grounds, but scarcely synchronized and without definite direction. In Alaska, average autumn movements in adults are of 0-9 km. Most movements at dawn and dusk.

Status and Conservation. Not globally threatened. Widespread and still fairly common throughout most of range. Estimated densities include 8-12 birds/km² in SC Alaska, up to 50 birds/km² in SW Alberta, and up to 38 birds/km² in Ontario. Some range contractions only in SE limits (Michigan, Minnesota, Wisconsin, S. Ontario) due to cutting of original conifer woodland, but species has recolonized some areas of secondary growth. Modern industrial forestry is clearly harmful, although clear-cut logging can, like fire, improve habitat, if carried out on small scale. Commonly hunted; annual bag figures at end of 1970's were of c. 188,000 birds in USA and c. 360,000 in Canada; apparently unlikely to affect populations seriously.

Bibliography. Allan (1985), Alway & Boag (1979), Amman (1963b), Anderson (1973), Boag (1991), Boag & Schroeder (1987, 1992), Boag *et al.* (1979, 1983), Crichton (1963), Ellison (1966, 1968, 1971, 1972, 1973, 1974, 1975, 1976), Ellison & Weeden (1979), Fenna & Boag (1974), de Franceschi & Boag (1991), Gurchinoff & Robinson (1972), Haas (1974), Hedberg (1980), Herman (1980), Herzog (1977a, 1978), Herzog & Boag (1978), Herzog & Keppie (1980), Hohf *et al.* (1987), Johnsgard (1973), Jonkel & Greer (1963), Keppie (1975a, 1975b, 1977a, 1977b, 1979, 1982, 1987a, 1987b, 1991), Keppie & Herzog (1978), Keppie & Towers (1990), Lattner (1982), Lemay (1989), Lumsden (1961a), Lumsden & Weeden (1963), MacDonald (1968), McCourt (1969), McCourt & Keppie (1975), McCourt *et al.* (1973), McKinnon (1983a, 1983b), McLachlin (1970), Naylor (1989), Naylor & Bendell (1987, 1989), Naylor *et al.* (1988), Nugent & Boag (1982), Pendergast (1969), Pendergast & Boag (1970, 1971, 1973), Pietz & Tester (1982), Quinn & Keppie (1981), Ratti *et al.* (1984), Redmond *et al.* (1982), Robinson (1969, 1980), Schroeder (1985a, 1985b, 1986), Schroeder & Boag (1985, 1991), Smyth & Boag (1984), Stepanyan (1962), Stoneberg (1967), Szuba (1989), Szuba & Bendell (1982, 1984, 1988), Terres (1980), Towers (1988), Zwickel & Brigham (1970, 1974).

Genus *DENDRAGAPUS* Elliot, 1864

3. Blue Grouse

Dendragapus obscurus

French: Tétrás sombre **German:** Felsengebirgshuhn **Spanish:** Gallo de las Rocosas
Other common names: Dusky Grouse (SE races); Sooty Grouse (W races)

Taxonomy. *Tetrao obscurus* Say, 1823, "Defile Creek", Colorado.

Perhaps close to genus *Falcipennis*, with which often merged (see page 376). Exceptional hybrids known with *Falcipennis canadensis*, *Tympanuchus phasianellus* and *Centrocercus urophasianus*. W coast races (*sitkensis*, *fuliginosus*, *howardi*, *sierrae*) formerly considered separate species, *D. fuliginosus*. Eight subspecies usually recognized.

Subspecies and Distribution.

D. o. sitkensis Swarth, 1921 - Alexander Archipelago (SE Alaska) to Queen Charlotte Is. (British Columbia).

D. o. fuliginosus (Ridgway, 1873) - coastal mountains from SE Alaska and S. Yukon to NW California; Vancouver I.

D. o. sierrae Chapman, 1904 - inner coastal ranges from C. Washington to California (Sierra Nevada).

D. o. howardi Dickey & van Rossem, 1923 - California, from S. Sierra Nevada S. to Tehachapi Mts and Mt Pinos.

D. o. richardsonii (Douglas, 1829) - S. Yukon and N. British Columbia through W. Alberta and E. British Columbia to N. Idaho and NW Wyoming.

D. o. pallidus Swarth, 1931 - S. British Columbia through E. Washington to NE. Oregon.

D. o. obscurus (Say, 1823) - Rocky Mts from C. Wyoming through Utah and Colorado S. to N. Arizona and W. New Mexico.

D. o. oreinus Behle & Selander, 1951 - NE Nevada.

Descriptive notes. Male 47-57 cm, c. 1300 g; female 44-48 cm, c. 840 g. Relatively large grouse; male mostly grey or slate-coloured, lacking black breast of *Falcipennis canadensis*; long, square tail has grey terminal band, except in races *pallidus* and *richardsonii*; cervical sacs thick, caruncled and near but yellow in coastal males (*fuliginosus* group), smoother and vinaceous to purplish during courtship in inland males (*obscurus* group); combs yellow in male, changing to orange and bright red during display. Female browner, barred on top of head, nape, scapulars, breast and flanks. Immature differs from adult in having more brownish back and wings, and shorter, narrower rectrices; juvenile superficially like adult female, with pale shaft streaks on upperparts, wings and tail, and narrow, pointed rectrices brown.

Habitat. Wide range of habitats in mountain zones; occurs from sea-level up to c. 3600 m, on average breeding at lower altitudes and spending winter in montane, often subalpine coniferous

forest. Distribution apparently associated with Douglas fir (*Pseudotsuga menziesii*) and true firs (*Abies*). Breeding habitat usually forested, but relatively open and dry; irregular relief and maximum amount of edge vegetation preferred, as well as variety of shrubs and presence of some deciduous trees, e.g. aspens (*Populus tremuloides*). In inland areas may occur in shrub-steppe and grassland areas, if not far from trees.

Food and Feeding. During winter almost entirely needles, but also buds, twigs and cones, of firs (*Pseudotsuga*, *Abies*), sometimes pines (*Pinus*), hemlocks (*Tsuga*) and, before shedding

needles, larches (*Larix*). Berries and herbaceous plants predominate in summer and autumn; on Vancouver I more than 90% of adult food consists of *Pteridium*, *Salix*, *Mahonia*, *Rubus*, *Vaccinium*, *Gaultheria* and *Hypochaeris*. Chicks take almost exclusively animal food during first 10 days, especially ants, beetles and grasshoppers; later change to berries. Birds tend to forage mostly during last 3 hours of daylight, and in early morning; growing young feed more continuously.

Breeding. Laying May-Jun. Promiscuous; males dispersed. Nest is shallow scrape, lined (often poorly) with dead vegetation and some feathers, usually under small conifers, shrubs, logs or overhanging rocks. Lays 6-8 eggs (4-10); incubation 25-27 days; down of chicks dorsally grey in coastal races and reddish brown in inland ones, mottled with black and brown; already has primaries 1-7 at hatching, first one shed at 16-17 days. Clutches that hatch, c. 60-80% in different studies; in late autumn, average brood 2.2-3.3 in coastal, and 3.2-4.3 in inland populations. At 1 year old, most females breed but few males do so. Annual adult survival rates: 66-75% in males, 40-71% in females; mean estimated longevity after first autumn: 3 years for males, 2 for females.

Movements. Altitudinal shifts between breeding and wintering grounds reported for most areas; in winter usually higher. In Washington, 15 of 30 recoveries occurred more than 8 km from ringing place (maximum 50 km).

Status and Conservation. Not globally threatened. Still occupies most of original range, with some contractions due to urbanization or agriculture. Race *howardi* apparently lost from S part of its range, for unknown reasons. Common throughout, although densities rather variable; usually c. 10 adult males/km² in interior, but values of 10-30 in coastal populations, and up to 83-103 in British Columbia. Mainly affected by forestry, sometimes positively, although temporarily, if this involves clear-cut logging on small scale; impact of forest exploitation in wintering montane areas should be investigated. Although a popular game bird everywhere, with annual bags of c. 520,000 birds in late 1970's, ringing recovery rates suggest low impact of hunting on populations, perhaps mainly due to autumn migration into rugged terrain. Grazing may be threat in some inland breeding areas of shrub-steppe and forest. Several attempted introductions: successful in parts of Arizona, New Mexico and British Columbia.

Genus LAGOPUS Brisson, 1760

4. Willow Grouse

Lagopus lagopus

French: Lagopède des saules German: Moorschneehuhn Spanish: Lagópodo Común
Other common names: Willow Ptarmigan; Red Grouse (*scoticus*)

Taxonomy. *Tetrao lagopus* Linnaeus, 1758, Swedish Lapland.

Hybrids relatively frequent with *Tetrao tetrix* and *Bonasa bonasia*; occasional with *Tetrao urogalus*. *Falcapennis canadensis* and *L. mutus*. Internal taxonomy confused, due to complicated plumage sequence, and based mainly on colour and pattern of summer plumages. Many races often lumped, although in quite different ways: nominate sometimes considered to include *koreni*, *birulai*, *kamtschatkensis*, *alascensis*, *albus*, *ungavus* and others, from Scandinavia to Quebec; races of SE Siberia also often merged, *sseerebrowsky* in *okadae* and *kozlovae* in *brevisrostris*. Irish birds occasionally awarded separate race, *hibernicus*. Nineteen subspecies currently recognized.

Subspecies and Distribution.

- L. l. scoticus* (Latham, 1787) - British Isles.
- L. l. variegatus* Salomonsen, 1936 - islands off Trondheim, Norway.
- L. l. lagopus* (Linnaeus, 1758) - Scandinavia, Finland, N European Russia.
- L. l. romanus* Serebrowsky, 1926 - Baltic countries and C Russia E to Kama Basin.
- L. l. birulai* Serebrowsky, 1926 - New Siberia Is.
- L. l. koreni* Thayer & Bangs, 1914 - Siberia from Urals and Yamal Peninsula to Pacific, S to Tomsk, Krasnoyarsk, Yakutsk and N coast of Sea of Okhotsk.
- L. l. maior* Lorenz, 1904 - SE Russia, N Kazakhstan and SW Siberia, E to Altai foothills.
- L. l. brevisrostris* Hesse, 1912 - Altai and Sayan Mts.
- L. l. kozlovae* Potenko, 1931 - W Mongolia, in Tannu-Ola, Khangai and Kentei Mts.
- L. l. sseerebrowsky* Domaniowski, 1933 - E Siberia, from L Baikal to Sea of Okhotsk, S to Khingan Mts. and Southern Ural.
- L. l. kamtschatkensis* Momiyama, 1928 - Kamchatka and N Kuril Is.
- L. l. okadae* Momiyama, 1928 - Sakhalin I.
- L. l. muriei* Gabrielson & Lincoln, 1959 - E Aleutian Is and Kodiak I.
- L. l. alexandrei* Grinnell, 1909 - coastal islands of SE Alaska and NW British Columbia.
- L. l. alascensis* Sward, 1926 - Alaska.
- L. l. leucopterus* Taverner, 1932 - Arctic islands of N Canada (Banks, Victoria, Southampton, Baffin) and adjacent mainland.

L. l. albus (Gmelin, 1789) - N Canada, from N Yukon and C British Columbia to Gulf of St Lawrence.

L. l. ungavus Riley, 1911 - N Quebec and N Labrador.

L. l. allenii Stejneger, 1884 - Newfoundland.

Descriptive notes. 36-43 cm; male 535-700 g, female 525-650 g. Rusty brown in summer, with white wings, belly and legs, and black tail; redder than similar *L. mutus* and with slightly heavier bill. All white during winter except for black tail. Plumage patchy during moults, in spring areas of reddish brown still mostly confined to head, neck and breast. Scarlet combs more prominent in spring and during courtship. Female greyer and more heavily barred, with very small combs. First-winter birds already like adults, but with less gloss on two outer primaries. Race *scoticus* has brown flight-feathers and never develops

white winter plumage; in at least two other races, *variegatus* and *gabrielsoni*, some dark feathers are retained during winter; race *scoticus* polymorphic.

Habitat. Primarily Arctic tundra, extending S in alpine mountain ranges and along or below tree-line, in openings of boreal forest. Prefers low, moderately moist areas, rich in low willows (*Salix*) or dwarf birches (*Betula*) in addition to berry-bearing shrubs, mosses, grasses and herbs; avoids rocky or lichen-rich tundra, as well as steep slopes. Male prefers territories in areas with vegetation lower than eye level and elevated sites such as rocks, trees or hummocks for displaying on. Nesting and brooding requirements fairly generalized, chicks using areas with very low vegetation. In winter prefers valley bottoms and riparian thickets of willows or, locally, birches, alders, aspens or spruces, often in forest glades. In British Is, depends on heather (*Calluna vulgaris*) moors, mainly in upland areas but also in bogs with *Eriophorum* and *Sphagnum*; in winter, also found at lower altitudes, sometimes in farmland. In Altai and other ranges in C Asia, occupies subalpine belt of vast thickets of *Betula rotundifolia*. In steppes of SW Siberia and N Kazakhstan was formerly found in relic patches of boreal vegetation, but these much reduced by farming, and where species survives now nests in grain fields.

Food and Feeding. Heavily dependent on willow, especially during winter, e.g. in Alaska, 94% willow buds and twigs, including 80% *Salix alaxensis*; in some areas, e.g. Scandinavia, birch can be preferred. Generally seems to depend less on low shrubs than *L. mutus*, and more on willow and birch; but *Vaccinium* is most important during winter in Newfoundland; heather is staple food all year round in British Is. Diet more varied from spring to autumn, when leaves and berries of *Vaccinium* and *Empetrum* are prominent. Some arthropods also taken in summer, mainly by chicks, although perhaps less often than by other grouse; in Scotland, even chicks under 3 weeks old eat mainly heather.

Breeding. Laying mostly May-Jun; Apr-May in British Is; second half of Jun in N Siberia. Monogamous; male guards incubating female and even broods chicks. Nest is shallow scrape, with thin lining, in thick vegetation, which usually covers it partially. Normally 8-11 eggs (2-15), most often 6-9 in *scoticus*; incubation c. 22 days; downy young with characteristic chestnut crown bordered by black lines, and narrow black line on centre of forehead; primaries, secondaries and greater upperwing-coverts break through on first day, well developed at c. 10 days; first primary shed at 18 days. First breeding at 1 year old. Annual adult survival rate c. 30% in different studies; mean longevity after first autumn, c. 10 months; one ringed bird survived 7 years, 8 months. Hatching success 78-3% in Norway, 82-5% in Scotland; chicks surviving 1 month, on average 54-4% in Norway (39-47-6-2%, depending on year).

Movements. Sedentary in some places, e.g. in Scotland and Scandinavia, where only short range altitudinal movements occur. At least partially migratory elsewhere: in N Siberia may move 200-300 km into forested areas; in North America occasionally reaches latitude of N Minnesota and S Ontario. Date and magnitude of movements may depend on food shortages, perhaps linked with population cycles, and mass migrations have occurred in some years. Females tend to move farther. Very limited daily movements.

Status and Conservation. Not globally threatened. Widespread and common to abundant throughout most of very extensive range. Nevertheless, some range contractions have been detected in parts of Europe, e.g. Baltic countries; these are often attributed to climatic changes. Abundance subject to marked threefold to fivefold fluctuations, often in 10 year cycles. In Canada, densities of c. 0.4-3 adults/km² throughout large areas containing unfavourable habitat, with up to 20-100 males/km² at some particular sites. In Russian tundra often reaches densities of 20-30 pairs/km², and up to 60 pairs/km². Other estimates include 52-95 birds/km² in poor to rich grouse moors in Scotland, 54-116 birds/km² in Norway, and 80 birds/km² in Newfoundland. Populations fluctuate around 200,000 pairs in Sweden, 110,000 in Finland (1958), and 500,000 in British Is (1970's). Most important tetraonid for hunting: in Russian tundra annual bags estimated at c. 8,000,000 birds (2,000,000 W of Ural); less intensively hunted in North America, where total of all *Lagopus* species amounts to c. 300,000 birds (c. 94,000 in Alaska, 200,000 in Canada). Race *scoticus* extensively managed and even bred in captivity for hunting, with up to 2,500,000 birds annually shot around 1911; poor habitat management and other factors reduced this figure to 260,000-600,000 by 1983, but some recovery reported since. Probably tolerates heavy levels of shooting, although important declines in Finland were attributed to excessive hunting. Many attempted introductions have taken place, most of them failing, e.g. *scoticus* in Germany and Belgium.

5. Rock Ptarmigan

Lagopus mutus

French: Lagopède alpin German: Alpenschneehuhn Spanish: Lagópodo Alpino

Taxonomy. *Tetrao mutus* Montin, 1776, Sweden.

Occasional hybrids known with *L. lagopus*, *Tetrao tetrix* and *Bonasa bonasia*. Very complex internal taxonomy, largely due to complicated moults. Many races vary only slightly in colour and pattern of summer plumage; sometimes lumped, though in rather different ways: races *komensis pleskei* and *transbaicalicus* sometimes included in *kelloggae*, or all of these in *nelsoni*, with possible addition of *krascheninnikovi* and *kurilensis*; race *reinhardi* sometimes included in *rupestris*, *macrorhynchus* in *nadezdae*, and *pyrenaicus* in *helveticus*. Thirty subspecies currently recognized.

Subspecies and Distribution.

- L. m. hyperboreus* Sundevall, 1845 - Svalbard (Spitsbergen), Franz Josef Land and Bear I.
- L. m. mutus* (Montin, 1776) - Norway, N Sweden, N Finland and Kola Peninsula.
- L. m. millaisi* Hartert, 1923 - Scotland.
- L. m. pyrenaicus* Hartert, 1921 - Pyrenees.
- L. m. helveticus* (Thienemann, 1829) - Alps, from Savoie to C Austria.
- L. m. komensis* Serebrovsky, 1929 - N Ural.
- L. m. pleskei* Serebrovsky, 1926 - N Siberia, from Taimyr Peninsula to Chukotsky Peninsula.
- L. m. macrorhynchus* Serebrovsky, 1926 - Tarbagatai.
- L. m. nadezdae* Serebrovsky, 1926 - mountains of S Siberia and Mongolia (Altai, Sayan, Khangai and others).

- L. m. transbaicalicus* Serebrovsky, 1926 - SE Siberia, from L. Baikal to Sea of Okhotsk.
 - L. m. krascheninnikovi* Potapov, 1985 - Kamchatka.
 - L. m. ridgwayi* Stejneger, 1884 - Commander Is.
 - L. m. kurilensis* Kuroda, 1924 - Kuril Is.
 - L. m. japonicus* Clark, 1907 - C Honshu (Japan).
 - L. m. evermanni* Elliot, 1896 - Attu I (Aleutian Is.).
 - L. m. townsendi* Elliot, 1896 - Kiska I (Aleutian Is.).
 - L. m. gabrielsoni* Murie, 1944 - Amchitka I (Aleutian Is.).
 - L. m. sanfordi* Bent, 1912 - Tanaga I and Kanaga I (Aleutian Is.).
 - L. m. chamberlaini* Clark, 1907 - Adak I (Aleutian Is.).
 - L. m. aikensis* Turner, 1882 - Atka I (Aleutian Is.).
 - L. m. yunaskensis* Gabrielson & Lincoln, 1959 - Yunaska I (Aleutian Is.).
 - L. m. nelsoni* Stejneger, 1884 - Unimak, Unalaska and Amaknak Is (Aleutian Is.).
 - L. m. dixonii* Grinnell, 1909 - Glacier Bay islands and adjacent mainland (SE Alaska).
 - L. m. kelloggae* Grinnell, 1910 - Alaska and N Yukon.
 - L. m. rupestris* (Gmelin, 1789) - N Canada, from Melville I and Ellesmere I to C British Columbia, S Mackenzie, Southampton I, N Quebec and Labrador.
 - L. m. captus* Peters, 1934 - E Greenland.
 - L. m. saturatus* Salomonsen, 1950 - NW Greenland.
 - L. m. reinhardi* (C. L. Brehm, 1824) - SW Greenland.
 - L. m. welchi* Brewster, 1885 - Newfoundland.
 - L. m. islandorum* (Faber, 1822) - Iceland.
- In 1992, a very small population of what appears to be a still undescribed race was discovered in Pamir Alai Mts, Tajikistan.

Descriptive notes. 33-38 cm; male 470-740 g; female 430-700 g. In summer, brown plumage like *L. lagopus*, but greyer, without reddish tones. During winter, all white; male has characteristic, conspicuous black laral stripes. Female even more difficult to separate from *L. lagopus*; slightly more yellowish grey, less rusty; in both sexes bill is slightly smaller. First-winter birds like adults, but outer two primaries differ in amount of pigment. Races separated mainly on slight differences in colour and pattern of summer plumage.

Habitat. Rocky tundra with fairly sparse vegetation, or alpine summits. More highly specialized for high Arctic conditions than *L. lagopus*; on average, lives farther N, up to 83° N on Ellesmere I and in N Greenland, and at higher altitudes. Rarely in areas of high shrubs or below tree-line. In Scotland, commonest in areas with large boulders or outcrops, in stunted heather, sometimes mixed with herbaceous vegetation. Almost always above 2000 m in S mountains, e.g. Alps and Pyrenees; above 5000 m in Pamir Alai. Since more dependent on ground vegetation for food than *L. lagopus*, during winter lives in less snowy regions, or looks for windswept ridges and slopes.

Food and Feeding. Winter food mainly taken from ground; varies greatly between localities, also depending on snow conditions. In Alaska, mainly buds and catkins of dwarf birch (*Betula*), followed by buds and twigs of willow (*Salix*); but in Iceland willows are preferred, probably because *L. lagopus* absent; *Vaccinium*, *Empetrum* and other berry-bearing shrubs are main winter food in Alps and other S areas. Diet usually much more varied from spring to autumn, consisting of leaves, flowers, berries and seeds of many plants, e.g. *Vaccinium*, *Empetrum*, *Arctostaphylos*, *Rhododendron*, *Geum*, *Carex*, *Polygonum*, *Equisetum*, *Dryas*, *Draba*, *Saxifraga*, etc.

Breeding. Laying mostly Jun, from late May in Scotland, from mid-Jun in Spitsbergen. Monogamous; male guards nest and incubating female, but not brood. Nest is shallow depression, scantily lined with grass, twigs, leaves and some feathers, usually in open, sheltered by large stone or shrub. Normally 5-8 eggs (3-11) in Scotland, and average of 6.4-9.0 in Alaska, varying with year; incubation 21-24 days; downy young similar to those of *L. lagopus*, also with brown crown bordered by black lines, but brown areas less rufous and pale patches greyer. Flight-feathers in growth at hatching; chicks able to fly at c. 10 days; first primary shed at 3 weeks. In Alaska, c. 67% of nests hatch and average brood size in Aug 4.8-6.1 in different years, 100% of 24 nests hatched in Scotland, where average brood size when chicks fully-grown is 1.2-6.2. Age of first breeding 1 year old; 38% survival rate from Aug to spring.

Movements. Most populations, including mountain ones, make only very limited movements, largely altitudinal and depending on local conditions and weather. Greater movements in Arctic populations, perhaps mostly nomadic or eruptive; one bird recovered over 1000 km S in Greenland. In North America, females reported to travel farther S and return later to breeding grounds.

Status and Conservation. Not globally threatened. Remoteness of habitat makes species relatively secure. A limited range contraction has been documented in Great Britain since end of 19th century, with local extinctions in Outer Hebrides, Rhum, Arran, SW Scotland, and English Lake District, perhaps due to excessive grazing by sheep. Densities change greatly, often in cyclical fashion: e.g. 5-18 birds/km² in one study area in Scotland, and 2.3-4.3 males/km² in another in Alaska. Apparently more stable in Alps, where 3-4 territories/km² estimated for good areas in Italy, and c. 5 males/km² for parts of Switzerland. In Japan, 15-16 birds/km²; in Taimyr, 6-8 birds/km²; in Kolyma region, 0.5-2.2 birds/km². Population estimates include c. 75,000 pairs in Sweden, 4000 in Finland, 10,000 in Scotland, less than 10,000 in France, and 7000-10,000 in Italy. Hunting probably does not affect populations except in small, isolated areas, where loss of habitat and increasing disturbance due to mountain tourism and ski-ing can locally be negative factors.

6. White-tailed Ptarmigan

Lagopus leucurus

French: Lagopède à queue blanche German: Weischwanz-Schneehuhn Spanish: Lagópodo Coliblanco
Other common names: Snow Grouse

Taxonomy. *Tetrao (Lagopus) leucurus* Richardson, 1831, Rocky Mountains, lat. 54° N. Validity of races questionable; all may be invalid. Five subspecies normally recognized.

Subspecies and Distribution.

- L. l. peninsularis* Chapman, 1902 - mountains in Alaska, Yukon and Mackenzie, S to Kenai Peninsula and S Yukon.
- L. l. leucurus* (Richardson, 1831) - Rocky Mts in British Columbia and SW Alberta.
- L. l. saxatilis* Cowan, 1939 - Vancouver I.
- L. l. rainierensis* Taylor, 1920 - Cascade Range, Washington.
- L. l. alipitensis* Osgood, 1901 - Rocky Mts, from Montana to N New Mexico.

Introduced (*alipitensis*) in parts of Oregon, California, Utah and New Mexico.

Descriptive notes. 31-34 cm; c. 325 g. Only *Lagopus* with all white tail. Winter plumage completely white; during summer both sexes have body mottled or barred with black, brown and buff, retaining white on wings, tail, belly and legs. Female in summer has larger buff margins on body feathers, resulting in a yellowish, more regularly barred pattern on back and sides. Immature shows some black pigment on outer two primaries. Racial variation clinal in both size and coloration: birds smaller in N, larger in S; breeding plumage darkest in S half of range, greyest in N.

Habitat. Alpine tundra; in Alaska, typically on steep slopes and ridges, often around cirques, with numerous rocky outcrops, and low, generally sparse vegetation, in which shrubs nearly absent. In Montana, prefers relatively flat areas above 2000 m, with rocks and moist ledges where alpine vegetation low but well developed; avoids boggy areas or shrubby vegetation over 45 cm high. In Colorado, both spring and winter distributions mainly conditioned by presence of alpine willows (*Salix nivalis*, *S. angulorum*) in snow-free areas. Nests mostly near tree-line, on moderate slopes.

Food and Feeding. In Alaska, where competes with the other two *Lagopus*, much of winter food consists of alder catkins (*Alnus*); willow (*Salix*) and birch (*Betula*) less important. In Colorado, alpine willows appear in 100% of food samples, while alder only locally abundant. In spring and summer, apart from willow leaves, important food includes leaves and flowers of *Ranunculus*, *Dryas*, *Potentilla*, *Saxifraga*, and bulbs of *Polygonum*. During first 2 weeks of life chicks feed largely on invertebrates. In some areas berries of *Empetrum nigrum* and *Vaccinium* eaten in autumn.

Breeding. Laying in Jun. Usually monogamous; male remains with female until hatching; pair-bond often lasts for more than one season. Frequently nests among or near rocks or boulders; nest is shallow depression, lined with materials gathered within 40 cm of nest. Lays 5-6 eggs (2-9); incubation 22-23 days; downy young less rufous above than other *Lagopus*, with less marked chestnut crown with black margins; chicks can fly at c. 10 days; first primary shed at c. 17 days. Clutches that hatch, 70% in Montana, 57% in Colorado. First breeds at 1 year. Annual adult survival rate 71%; estimated mean longevity after first summer 3 years; estimated maximum longevity 13-15 years.

Movements. Only limited altitudinal movements in winter. Females and subadults move further on average, e.g. in Colorado, adult males move under 2.5 km, whereas subadult females 8.5 km, maximum 22-27 km.

Status and Conservation. Not globally threatened. Highly disjunct range throughout Rocky Mts makes some small S populations vulnerable, e.g. in New Mexico, where once found on all alpine ridges of Sangre de Cristo Mts, but presently occurs only around a few peaks. In Colorado, where more than 10,000 km² are occupied by species, densities average c. 6.5 birds/km² (2-12), with low amplitude cycles. Annual hunting bag in Colorado was of c. 1000 birds in 1970-1974, so shooting probably does not represent a relevant threat in general. Several introduction attempts have been successful.

Bibliography. Bridbury (1915), Braun (1969, 1985), Braun & Rogers (1971), Braun, Hoffman & Rogers (1976), Braun, Martin & Robb (1993), Braun, Nish & Giesen (1978), Braun, Schmidt & Rogers (1973), Choute (1960, 1963a, 1963b), Clarke & Johnson (1992), Frederick & Gutiérrez (1992), Giesen (1977), Giesen & Braun (1979a, 1979b, 1979c, 1992, 1993), Giesen *et al.* (1980), Hertzog *et al.* (1970), Hertzog, Hoffman & Braun (1965, 1970), Hoffman & Giesen (1983), Jensen & Ryder (1965), Martin *et al.* (1990), May (1975), May & Braun (1972), Moss (1973, 1974), Quick (1947), Ridgway & Friedmann (1946), Root (1988), Schmidt (1969, 1988), Scott (1982), Terres (1980), Weeden (1967).

Genus *TETRAO* Linnaeus, 1758

7. Eurasian Black Grouse

Tetrao tetrix

French: Tétrás lyre

German: Birkhuhn

Spanish: Gallo-lira Común

Other common names: Blackcock (male); Greyhen (female)

Taxonomy. *Tetrao Tetrix* Linnaeus, 1758, Sweden.

Often placed in genus *Lyrurus* together with *T. mlokosiewiczii*, with which forms superspecies. Commonly hybridizes with *T. urogallus*, and quite often with *Lagopus lagopus*, both hybrids even receiving vernacular names; also occasionally with *L. mutus* and *Bonasa bonasia*. Race *tschusti* often included in *viridanus*, and *baikalensis* in *ussuriensis*. Seven subspecies currently recognized.

Subspecies and Distribution.

T. t. britannicus (Witherby & Lönnberg, 1913) - N & W Great Britain.

T. t. tetrix Linnaeus, 1758 - most of range, from Scandinavia, Belgium and Alps of S France to NE Siberia (R. Kolyma).

T. t. viridanus Lorenz, 1891 - SE Russia and SW Siberia, between R Don and R Irtysh.

T. t. tschusti Johansen, 1898 - S Siberia, from R Irtysh to L Baikal, N to Tomsk and Krasnoyarsk, S to NW Altai and Sajan Mts.

T. t. baikalensis Lorenz, 1911 - SE Siberia, from L Baikal to Amurland, S to N Mongolia and NW Manchuria.

T. t. mongolicus Lönnberg, 1904 - Kirgizh and Tien Shan E to Altai and other ranges in W Mongolia.

T. t. ussuriensis Kohts, 1911 - Manchuria, from Khingan (Chingan) Mts to R Ussuri and NE Korea.

Descriptive notes. Male c. 60 cm. 1100-1250 g (up to 1800 g); female, c. 45 cm. 750-1100 g. Glossy black, with blue or green reflections, contrasting with white in rounded carpal patch, prominent wingbar and undertail-coverts; peculiar lyre-shaped tail, with outer feathers long and curved outwards; scarlet combs. In late summer, feathers on head and neck mottled or barred brown, and some white on throat. Female largely brown, heavily barred black; darker than *T. urogallus*, with thin white wingbar and shorter tail, slightly forked when closed. First-winter birds like adults, but male browner and duller, with outer tail feathers less curved; in both sexes, two outermost primaries more sharply pointed and more vermiculated at tips. Races vary clinally in size, colour of gloss in male and general coloration of female.

Habitat. Highly variable throughout wide range, but typically found in transition area between forests and open environments, e.g. steppes, heaths, moors, bogs and marginal cultivation. From N edge of boreal forest to brushwood steppe zone or locally semi-desert; in lowlands and mountains, up to 2000 m in Alps, 3000 m in Tien Shan. In N Europe, deciduous or mixed forests preferred to coniferous ones, and sparse, young stands to older, denser ones; but in S mountains, e.g. Alps, mainly occupies moderately dense forest of spruce and fir, or larch. In many areas appears to select birches (*Betula pubescens*, *B. verrucosa*). Good breeding habitat usually contains a high diversity of plants.

Food and Feeding. In many places favourite winter food is birch catkins, followed by birch buds and shoots, and needles, cones and male flowers of conifers, e.g. *Pinus sylvestris* and *P. mugo*. In less snow-covered areas in S of range, e.g. Scotland and Netherlands, greater winter use of shrubs (*Calluna*, *Rhododendron*, *Vaccinium*) and grasses. During spring, importance of birch declines in favour of berries, stems and shoots of *Vaccinium myrtillus*, *V. uliginosum*, *V. vitis-idaea*, *Empetrum nigrum*, *Calluna vulgaris*, *Juniperus communis*, *Polygonum viviparum*, etc. Chicks of under 100 g eat mostly insects, especially ants; older ones switch to berries, drupes, nutlets, etc. Shift to tree-feeding in winter is probably related to amount of food on ground, leaf conditions of trees and weather and snow conditions.

Breeding. Laying May-Jun. Promiscuous; males form leks. Nests amongst scrub or tall vegetation, often at base of tree, between roots, under low branches or against a boulder; nest is a shallow scrape, usually lined with some plant material and feathers. Average 8 eggs (6-11) in Finland; incubation 25-27 days; downy chick has brown cap surrounded by black line, reminiscent of *Lagopus*; flight-feathers develop from 1st day, and chicks capable of flight at 10-14 days; first primary shed at c. 15 days. In two studies in Finland, 71% clutches hatched and 62% chicks survived until late Aug. Sexual maturity in first year, but males probably rarely mate even during second. Annual survival rate 40-60% (Finland); one ringed female survived at least 5-5 years.

Movements. Largely sedentary, although apparently eruptive in some N areas at long intervals, when large flocks (females heavily outnumbering males) may move hundreds of kilometres; furthest recovery over 1000 km, in Sweden. Regular winter migrations reported in parts of Siberia (Ussuri, Amur). In Norway, males recovered at 1-6 km on average, females at 4-4 km. In general, daily movements limited, but in steppes of N Kazakhstan, regular flights of up to 30 km said to occur.

Status and Conservation. Not globally threatened. Major declines and range contractions reported all over Europe, except in Alps and N. Following some expansion during 19th century, species presently very scarce in most of C Europe: e.g. in Denmark from c. 2500 birds in 1964 to 280-360 in 1977; in Netherlands from c. 3000 birds in 1964 to 280-360 in 1977. In Alps, where typical densities appear to be 1-5-7 males/km², population may be stable: less than 1000 pairs in France, c. 40,000 birds at end of summer in Italy, c. 14,000 birds in Austria. Much commoner, although also decreasing, in Fenno-Scandia, with possibly 500,000 birds in Norway, c. 300,000 pairs in Sweden, and c. 900,000 pairs in Finland, where densities may average 1-3 males/km². In Russia, numbers and range diminishing in S, but apparently increasing in N. In Ukraine, now scarce, occurring only in Poles'ye zone and Carpathians; protected in many areas, and species not hunted. Logging in mature woodland tends to favour present species, but increased cultivation, afforestation of heathlands, removal of birch stands and imposition of coniferous monocultures have negative effects. Locally, species also suffers from excessive hunting, disturbance at leks and other factors. Hunting figures, mostly from late 1970's, include annual bags of 1200-1500 males in Switzerland, 1700 males in Austria, 1200-1600 males in Poland, 19,000 birds in Norway, 21,600 in Sweden and 54,000-171,000 in Finland. In C Europe mainly hunted in spring.

8. Caucasian Black Grouse

Tetrao mlokosiewiczii

French: Tétrás du Caucase

German: Kaukasusbirkhuhn

Spanish: Gallo-lira Caucasiano

Taxonomy. *Tetrao mlokosiewiczii* Taczanowski, 1875, Lagodekhi, eastern Caucasus.

Often placed in genus *Lyrurus* alongside *T. tetrix*, with which forms superspecies. Monotypic.

Distribution. Great and Little Caucasus Mts, S into NE Turkey and NW Iran.

Descriptive notes. 38-53 cm, with female smaller; male 820-1005 g, female 750-784 g. Very similar to *T. tetrix*, but plumage greener black; lacks white on wingbar and undertail-coverts; long tail has shorter "lyres", which partly curve downwards. Female grey-brown, narrowly barred black; tail almost square-ended. First-winter bird and juvenile very similar to female.

Habitat. Typically in transition between upper limits of mountain forests (*Picea orientalis*, *Betula*) and subalpine meadows with rhododendron (*Rhododendron caucasicum*) thickets and stunted birch; after chicks hatch,

brood can move onto alpine meadows. In NW Caucasus, most birds live within vertical range of 300-500 m, centred on the tree-line. In summer, mainly found in subalpine meadows, while during winter tends to concentrate in upper parts of forests; on Great Caucasus in Azerbaijan, occurs at 1700-3300 m, especially at c. 2400 m, but in winter descends to 800-1000 m.

Food and Feeding. In winter, mainly buds and catkins of birch (*Betula*), and fruits and needles of juniper (*Juniperus*); also dog-rose (*Rosa*) fruits, rhododendron leaves, spruce (*Picea*) needles and leaves of *Vaccinium*. During summer, mainly pods, stalks, flowers, berries and seeds of alpine plants, including *Daphne*, *Vaccinium* and *Fraxinus*. Insects rarely taken by adults; during first 10-15 days, chicks eat almost exclusively insects, mainly beetles, later moving onto berries. In autumn, as birds descend into forest, they take spruce needles, crab-apple leaves and acorns. Main foraging periods, at least during winter, are shortly after daybreak and in evening.

Breeding. Laying in May. Nest is a shallow scrape, lined with grass and feathers, concealed in bushes (e.g. rhododendron, juniper) or sometimes under a rock. Normally 6 eggs (2-10); incubation 20-25 days; downy chick almost identical to that of *T. tetrix*, perhaps paler and with cap less distinctly bordered with black; chick apparently able to fly at 10-14 days. Success: of 80 eggs, 60 hatched; in Jul, average brood size 3-7. Sexual maturity in first year, but males probably do not mate until at least second.

Movements. Only limited altitudinal movements of up to 2 km recorded.

Status and Conservation. INSUFFICIENTLY KNOWN. Included in USSR Red Data Book and protected by hunting regulations in most places. In late 1970's, was still reasonably numerous in suitable areas, but has now disappeared from some mountains at N and S limits of range. In Azerbaijan, total population reckoned to be 1500-2000 birds; declining outside protected areas, due to intensive grazing of subalpine meadows, and predation of young by sheepdogs; fairly intense hunting pressure, especially in Little Caucasus. In Zakataly Reserve, NW Azerbaijan, recent censuses gave 252 birds in 1982, 257 in 1988, 136 in 1989 and 221 in 1990; only c. 30% of these were females, so total population probably somewhat higher; density of 20 birds/3-5 km route. Recent survey of Kackar Mts in NE Turkey yielded 134 males at 6 sites; at least 50 males seen displaying at Sivrikaya. Monitoring of populations required.

Bibliography. Averin (1938), Belik (1986b), Bergmann *et al.* (1991), Cramp & Simmons (1980), Dementiev & Gladkov (1952), Flint *et al.* (1984), Hue & Etchecopar (1970), Kinkov (1975), Klaus *et al.* (1988, 1990), Kutubidze (1961), Kuz'mina (1992), Patrikeev (1993), Potapov (1978, 1982b, 1985), Potapov & Flint (1989), Potapov & Pavlova (1977), Scott (1976), Temple & Cocker (1991), Tkachenko (1966), Vitovic (1986).

9. Western Capercaillie

Tetrao urogallus

French: Grand Tétrás

German: Auerhuhn

Spanish: Urogallo Común

Taxonomy. *Tetrao Urogallus* Linnaeus, 1758, Sweden.

Forms superspecies with *T. parvirostris*, with which very commonly hybridizes where ranges overlap in Siberia (up to 12% of males reported to be hybrids in one area); hybrids also common with *T. tetrix* and occasional with *Lagopus lagopus*. Many of proposed races clearly intergrade, and sometimes reduced essentially to two, with nominate in N and *taczanowskii* in S, but this option probably oversimplistic. Twelve subspecies currently recognized.

Subspecies and Distribution.

T. u. cantabricus Castroviejo, 1967 - Cantabrian Mts (NW Spain).

T. u. aquitanicus Ingram, 1915 - Pyrenees.

T. u. major C. L. Brehm, 1831 - C Europe, from Germany and Alps to SW Baltic states, W Byelorussia, E Carpathians and N Macedonia.

T. u. rufifrons Dobrowski, 1912 - Carpathians in Ukraine and Romania, and Rhodope Mts in Bulgaria.

T. u. urogallus Linnaeus, 1758 - Scandinavia; Scotland (where reintroduced).

T. u. lonnbergi Snigirevski, 1957 - Kola Peninsula.

T. u. karelicus Lönnberg, 1924 - Finland and Russian Karelia.

T. u. pleskei Stegmann, 1926 - Byelorussia, N Ukraine and most of European Russia.

T. u. obsoletus Snigirevski, 1937 - from L Onega through N Russia and N Siberia to upper R Lena.

T. u. volgensis Buturlin, 1907 - C & SE Russia.

T. u. uralensis Menzbier, 1887 - S Urals and SW Siberia E to Barnaul.

T. u. tuzanowskii Stejneger, 1885 - C Siberia, S to Altai Mts and NW Mongolia.

dusky bill; in both sexes first-winter bird has outer two primaries speckled reddish brown. Juvenile shows pale shaft streaks on mantle. Races separated mainly on darkness of plumage and size.

Habitat. Forest and woodland, mainly coniferous (especially *Pinus sylvestris*, but also *Picea*, *Abies*, etc.) or mixed coniferous-deciduous; also isolated broad-leaved forests in parts of range, e.g. Cantabrian Mts (N Spain) and S Urals. Prefers extensive areas of old, shady forest, often with damp soil and interspersed with bogs, areas of peat or glades, and with a dense undergrowth of ericaceous plants (*Vaccinium*, *Calluna*). In winter, may select more open forest, at least in N, while during summer denser forest with abundant fruit bushes are preferred, especially by broods and moulting birds.

Food and Feeding. During winter mainly pine needles, constituting up to 100% in Finland, mostly *P. sylvestris*, but also *P. cembra*, *P. uncinata*, etc. Tree-feeding in winter can last for 5 months in N, until absence of snow allows feeding on ground. In S, winter diet more varied, e.g. in Cantabrian Mts, holly (*Ilex aquifolium*) leaves and birch (*Betula*) buds during snowy periods, but otherwise buds of blueberry/bilberry (*Vaccinium myrtillus*) and heaths (*Erica*). Inter-seasonal and summer food includes needles, leaves, stems and berries of a variety of plants, including juniper (*Juniperus communis*), blueberry, whortleberry (*Vaccinium uliginosum*), crowberry (*Empetrum nigrum*), cloud-berry (*Rubus chamaemorus*), cow-wheat (*Melampyrum pratense*), woodrush (*Luzula*), sedges (*Carex*), horsetails (*Equisetum*), mosses, etc. Insects are important only for small chicks.

Breeding. Laying mainly in May (mid-Apr to mid-Jun). Promiscuous; males form ill-defined leks. Nest is shallow depression, scantily lined with grass, pine needles, twigs or some feathers, in thick cover, often at base of tree. Normally 6-9 eggs (4-12); incubation c. 26 days; downy chick lacks brown on crown and has characteristic black V-mark on forehead; flight-feathers and upperwing-coverts start to develop at hatching, and chick able to fly at 2-3 weeks; first primary shed at 17 days. Clutches that hatch, 84-94% for different years in Finland, where other study revealed 60% of eggs laid produced chicks that were still living in late Aug. Sexual maturity in first year, but males do not mate before three. Annual survival rate c. 60% in adult males; one survived to 13-5 years old; in captivity may live up to 18 years or more.

Movements. Mainly sedentary, but often with local movements in winter in response to feeding requirements, e.g. in Siberia, regularly moves from deciduous to coniferous woodland for winter. Females tend to move farther than males. Also some irregular movements, on occasion of over 1000 km, which may be eruptive; wandering birds even enter villages, where recorded crashing into buildings.

Status and Conservation. Not globally threatened. Still occupies most of original range, although serious declines in W Europe have led to extinctions in Ireland, Great Britain, Belgium, most of France and Germany, Hungary and many other areas; now mainly confined to mountains and N areas. Race *cantabricus* of Cantabrian Mts considered endangered in Red Data Book of 1978/79; c. 600 males in 1980. In Pyrenees, c. 2500 birds estimated in Spain, and c. 5000 in France; in Alps, c. 250 males in France, c. 1100 males in Switzerland, 6500-9000 birds in Italy, and c. 10,000 males in Austria; perhaps under 2200 males in Germany. In Scotland, where extinct from 1785, successfully reintroduced around 1837 and presently numbers c. 1000-2000 birds, but declining. Also declining, though generally more secure, in Fennoscandia, where during 1960's estimated 300,000-400,000 males in Norway and 600,000 in Finland. In Ukraine, occurs in Poles'ye zone and Carpathians, where was common and fairly numerous at turn of century; has declined rapidly since 1960's, due to deforestation, amelioration of climate, pesticides, disturbance and poaching; total population now reckoned to number 4400-5300 birds; protected in 3 nature reserves and suffers no hunting pressure. Many estimates of densities available, ranging from 0.1 males/km² in primeval forest of Bialowieza (NE Poland) to 24 birds/km² in natural pine forests in Scotland, but most typically c. 0.5-1.0 males/km². Still commonly hunted, except in SW Europe, with annual bags: in Sweden c. 16,000 birds in 1978-1980; in Norway c. 13,000 in 1980, but c. 40,000 around 1960; and in Finland 14,500-33,000 in 1969-1976, but up to 104,000 during early 1960's. Main threat is destruction or alteration of woodland. Afforestation has locally fostered some recoveries, but modern forestry practices generally detrimental. Other factors possibly involved in declines include excessive shooting, disturbance, pollution (acid rain) and perhaps climatic changes.

10. Black-billed Capercaillie

Tetrao parvirostris

French: Tétras à bec noir

German: Steinadlerhuhn

Spanish: Urogallo Piquin Negro

Other common names: Siberian/Small-billed Stone-bird/Rock Capercaillie

Taxonomy. *Tetrao parvirostris* Bonaparte, 1856, Muka-Sanaga, west of Aldan and Amginskoje, east Siberia.

Synonym *T. urogalloides*. Forms superspecies with *T. urogallus*, with which frequently hybridizes in the limited areas of overlap in basin of R Yenisey. Birds from various parts of Siberia formerly awarded races *tarensis*, *janensis* and *kolymensis*, and those from Transbaikalia race *macrurus*. Three subspecies currently recognized.

Subspecies and Distribution.

T. p. parvirostris Bonaparte, 1856 - E Siberia, from lower R Yenisey to the upper R Anadyr, S to Transbaikalia, Manchuria, Ussurieland and Sikhote-Alin Mts; Sakhalin I.

T. p. kamshaticus Kittlitz, 1858 - Kamchatka.

T. p. stegmanni Potapov, 1985 - L Baikal area, Sajon Mts and N Mongolia, from Khangai Mts to Kentei Mts.

Descriptive notes. 68-97 cm, female much smaller; male 3350-4580 g, female 1700-2200 g. Similar to *T. urogallus*; blackish, with underparts predominantly black, but white tips to secondaries and conspicuous white marks on scapulars, greater wing-coverts and uppertail-coverts. Bill black; red combs relatively small. Female like that of *T. urogallus*, but darker, more heavily marked on upper breast, and with larger white marks on wing coverts and secondaries. Races differ mainly in extent of white on upperwing and flanks.

Habitat. Distribution related to larch (*Larix gmelini*) taiga forest, both in plains and

mountains, extending from wooded tundra in N to woody steppes in S Transbaikalia. In some regions also in pine, cedar or mixed deciduous-coniferous forests. In parts of Kamchatka, found in park-like birch stands, primarily of *Betula ermani*. Apparently, in general adapted to more open environments than *T. urogallus*.

Food and Feeding. Limited information available. Probably has more adaptable winter diet than *T. urogallus*, largely relying on larch buds and shoots, but also taking pine and fir needles, birch catkins and buds, fruits of wild roses and other items. From spring to autumn eats berries and leaves of *Vaccinium*, *Empetrum nigrum*, *Juniperus*, etc.; also some invertebrates, e.g. caterpillars, midges, ant eggs.

Breeding. Laying May-Jun. Promiscuous; males form ill-defined leks. Nest is small depression, lined with needles, moss, grass and some feathers, often below drooping branches of fir, fallen logs or branches, or under crown of a fallen tree. Lays 6-7 eggs (5-10); incubation c. 24 days; downy young similar to those of *T. urogallus*, but with rufous crown patch, and more rufous, less streaked back; capable of flight at c. 10 days.

Movements. Probably sedentary, although very little information available. Altitudinal movements reported from Kamchatka, where females winter at higher elevations.

Status and Conservation. Not globally threatened. Formerly very common and much hunted, especially in S areas. However, populations have decreased, perhaps partly as result of natural fluctuations. Establishment and enforcement of hunting regulations needed.

Bibliography. Andreev (1975a, 1977a, 1979, 1991a), Dementiev & Gladkov (1952), Etchecopar & Hül (1978), Flint *et al.* (1984), Gao *et al.* (1988), Johnsgard (1983a), Kirikov (1975), Kirikov & Shubnikova (1968), Klaus *et al.* (1989), Kuz'mina (1992), Larionov (1962), Lobko-Lobanovskij & Zilin (1962), Porkert (1992), Potapov (1985), Potapov & Flint (1989), Rogacheva (1992).

Genus BONASA Stephens, 1819

11. Hazel Grouse

Bonasa bonasia

French: Gelinotte des bois

German: Haselhuhn

Spanish: Grévol Común

Other common names: Hazel Hen

Taxonomy. *Tetrao bonasia* Linnaeus, 1758, Sweden.

Formerly placed in genus *Tetrastes*. Forms superspecies with *B. sewerzowi*. Occasional hybridization reported with *Lagopus lagopus*, *L. mutus* and *Tetrao tetrix*. Complex internal taxonomy, with various attempts to lump races, e.g. only four recognized: with *styriaca*, *rhenana* and *schiebeli* placed in *rupestris*; *volgensis* and *griseonota* in *bonasia*; *kolymensis* in *sibirica*; *amurensis* and *yamashinai* in *vicinitas*. Twelve subspecies currently recognized.

Subspecies and Distribution.

B. b. styriaca (von Jordans & Schiebel, 1944) - Jura Mts, Alps, Hungary, Slovakia and S Poland.

B. b. rhenana (Kleinschmidt, 1917) - NE France, Luxembourg, Belgium and W Germany.

B. b. rupestris (C. L. Brehm, 1831) - S Germany, Bohemia and Sudety Mts.

B. b. schiebeli (Kleinschmidt, 1943) - Balkan Peninsula.

B. b. volgensis (Buturlin, 1916) - Poland and Ukraine to C European Russia.

B. b. bonasia (Linnaeus, 1758) - S Scandinavia, Finland and N European Russia to Urals.

B. b. griseonota Salomonsen, 1947 - N Sweden.

B. b. sibirica (Buturlin, 1916) - most of forested Siberia S to Altai and Sajon Mts, N Mongolia and N Amurland.

B. b. kolymensis (Buturlin, 1916) - extreme E Siberia, from N Yakutia and Verkhoyansk Mts to Sea of Okhotsk.

B. b. amurensis (Riley, 1916) - S Amurland and Little Khingan Mts S to N Korea.

B. b. yamashinai (Moriyama, 1928) - Sakhalin I.

B. b. vicinitas (Riley, 1915) - Hokkaido (N Japan).

Descriptive notes. 35-40 cm; 370-430 g; female only slightly smaller. Variably brownish grey, with fine dark barring on crown, neck, mantle and uppertail-coverts, underparts barred or spotted with dark grey and ochre; chin black, bordered with white; white lines below and behind eyes and on sides of neck; tail relatively long and rounded, white fringed, with a black subterminal band, broken by brown central pair of rectrices. Small erectile crest; small red combs; greyish black bill. Female brownish, with whitish throat. First-winter bird almost identical to adult, with some minor differences in two outermost primaries; juvenile like adult female, with white shaft streaks on back. Races differ mainly in size and intensity of grey and brown tones.

Habitat. Mostly mixed coniferous-deciduous woodland, both in plains and in mountains, up to 1600-1800 m in Alps. Habitat varies in different parts of extensive range, but species seems to avoid pure coniferous stands, and does occur in areas without conifers, e.g. parts of W Europe and mountainous regions of N Mongolia and Transbaikalia. Large, dense forests with rich, varied undergrowth and occasional clearings are generally preferred, as are presence of thickets of alder

(*Alnus*), birch (*Betula*), aspen (*Populus*), hazel (*Corylus*) and other "catkin" trees; along streams and rivers, in transitional areas or in clearings caused by fires, avalanches or lumbering.

Food and Feeding. During winter almost exclusively catkins, buds and twigs of alder, birch or both; also hazel, aspen, etc. In spring, these are gradually replaced by leaves of same trees, and, depending on snow conditions, leaves and flowers of ground vegetation. Berries and other fruits important during summer and autumn, mainly those of *Vaccinium*, but also *Ribes*, *Fragaria*, *Rubus*, *Sorbus*, *Crataegus*, *Prunus* and others, varying considerably from region to region depending on availability. Chickens eat almost exclusively arthropods during first 10 days, mainly ants and their larvae, but also beetles, caterpillars, grasshoppers and spiders; thereafter, progressively more vegetarian. In autumn, nuts, acorns and seeds can be of importance, e.g. *Carpinus*, *Acer*, *Quercus*, *Fagus*, conifers, etc. Daily food c. 41 g in winter, 58 g in spring, 28 g in summer, and 27 g in autumn.

Breeding. Laying Apr-May in C Europe. May-Jun in Scandinavia and Siberia. Monogamous; male usually leaves territory during incubation. Nest is a shallow scrape, lined with grass, leaves and other plant material, well concealed by undergrowth or under roots of fallen tree. Lays 7-11 eggs (5-14); incubation c. 25 days; downy young have brown crown cap not bordered by black; flight-feathers present at or shortly after hatching; chicks capable of flight at c. 15 days. Average brood size (when still dependent) 4-7 in one study. First breeding at one year old. Annual adult survival rate probably c. 30%; one ringed bird survived 7 years, 3 months.

Movements. Highly sedentary: in Russia, 88% of recoveries within 500 m of ringing site, maximum 1500 m; average of 20 recoveries in Sweden and Finland, 1-2 km, maximum 10 km. Females and juveniles tend to disperse farther.

Status and Conservation. Not globally threatened. Marked declines and some range contraction in many parts of W & C Europe, e.g. extinctions in Pyrenees, Massif Central and some lowland areas of Germany. Populations of under 10,000 pairs in France, 5000-6000 in Italy, c. 200 in Belgium, c. 30,000 in Estonia, c. 150,000 in Sweden, and c. 230,000 in Finland; generally much more numerous eastwards, but very rare in Ukraine, where occurs only in Poles'ye zone and Carpathians, with highest density of 2 pairs/km². Abundance varies markedly between years. Spring densities in Switzerland range from c. 2 pairs/km² in lowlands to over 5 pairs/km² in forests above 1000 m; up to 30 birds/ha in a mixed forest area of Poland. Autumn densities in N European mixed forests usually average 4-6-37 birds/km²; in C European montane forests 10-11 birds/km². Hunting not likely to affect populations, given secretive habits of species; some annual bag figures during 1970's include c. 10,200 birds in Norway, c. 18,000 in Sweden and 28,000-69,600 in Finland, but more intensively hunted in European Russia and Siberia. Apparently very sensitive to habitat changes, especially modern forestry trends, although small-scale timber work could have positive effects.

Ahnlund & Helander (1975), Andreev (1977b), Andreev & Krehmar (1976), Aschenbrenner *et al.* (1978), Aubin (1970, 1972), Bauer (1960), Bergmann *et al.* (1975, 1982), Bonczar & Swenson (1992), Bonczar & Wrobel (1991), Brazil (1991), Catusse *et al.* (1992), Cramp & Simmons (1980), Donaurov (1947), Eichéopar & Hue (1978), Flint *et al.* (1984), de Franceschi (1986, 1988), Gajdar (1974a, 1974b), Gavrin (1969), Heim de Balsac (1935), Ivanter (1962, 1963), Jacob (1987), Koch (1978), Krätzig (1939), Kuz'mina (1992), Leclercq (1988b), Ledant (1990), Linden (1981b), Potapov & Flint (1989), Pynnönen (1954), Rodionov (1963), Rogacheva (1992), Romanov (1963), Salo (1971), Schatt (1991a, 1991b, 1993), Scherzinger (1981), Simeonov *et al.* (1990), Stenman & Helminen (1974), Swenson (1991a, 1991b, 1991c, 1992, 1993), Swenson & Andreev (1991), Swenson & Boag (1993), Swenson & Danielson (1991), Swenson & Olsson (1991), Teidoff (1951), Tomek (1965), Uusvaara (1963), Wiesner *et al.* (1977), Wilowski (1968), Zbinden (1979).

12. Severtsov's Grouse

Bonasa sewerzowi

French: Gélinotte de Severtzov **German:** Schwarzbrust-Haselhuhn **Spanish:** Grévol Chino
Other common names: Severtsov's Black-breasted Hazel Grouse

Taxonomy. *Tetrastes sewerzowi* Przevalski, 1876, mountains of Gansu, central China. Closely related to *B. bonasia*, with which forms superspecies. In past, birds of S and W often awarded separate race, *secunda*. Monotypic.

Distribution. Mountains of C China, from C Gansu and S Qinghai to E Tibet, NW Yunnan and N Sichuan.

Descriptive notes. 34 cm, c. 270 g. Very similar to *B. bonasia*; upperparts more broadly barred black and upper breast more chestnut, with only small white tips to feathers; tail has quite different barred pattern.

Habitat. Birch and coniferous mountain forests, generally above 1000 m, and as high as 4000 m in Tibet; the altitude occupied increases with decreasing latitude, e.g. breeds at 2350-3000 m in Qilian Mts of NW Gansu, but at 3530-3820 m in NW Yunnan. In places, may reach tree-line and during summer even alpine belt, in areas of rhododendron. In Gansu, main habitats types centred on dragon

spruce (*Picea crossata*), sometimes with 60-90% cover of moss (*Vaccinella*, *Braun*) on forest floor; other typical plants include birch (*Betula*), willow (*Salix*) and barberry (*Berberis*); grassland and alpine shrubs generally avoided.

Food and Feeding. In Gansu, mainly flower and leaf buds of willow and birch in early spring, moving onto flower buds and leaves of the same species by May, in Jun-Jul, seeds and inflorescences of *Polypodium* dominate. Forages on ground or in trees.

Breeding. Laying from end May to Jun. Monogamous. Nest at base of tree, in tree stump or on rocky ledge; made of grass, sometimes lined with pine needles and partly edged with moss. Lays 5-8 eggs; incubation 25 days (artificial); downy chicks have head markings more apparent than in other *Bonasa*.

Movements. Apparently sedentary.

Status and Conservation. Not globally threatened. Very little information available. Common in suitable forest; has disappeared from E Qinghai and C Gansu, due to deforestation, and also suffering intensive habitat loss in SW Gansu. Simultaneous preparation of eggs by Large-rumped Crows (*Corvus macrorhynchos*), accounting for failure of 50% of nests located during recent study.

Bibliography. Beick (1927), Cheng Tso-hin (1987), Eichéopar & Hue (1978), Johnsgard (1983a), Liu & Gong (1994), Meyer de Schauensee (1984), Ræthel (1988), Schonwetter (1929), Short (1967), Stressemann *et al.* (1938).

13. Ruffed Grouse

Bonasa umbellus

French: Gélinotte huppée

German: Kragenhuhn

Spanish: Grévol Engolado

Taxonomy. *Tetrao umbellus* Linnaeus, 1766, Pennsylvania.

Only know to have hybridized, very rarely, with *Falcipecten canadensis*. Fourteen subspecies currently recognized.

Subspecies and Distribution.

B. u. yukonensis Grinnell, 1916 - W Alaska and C Yukon to N Alberta and NW Saskatchewan.
B. u. umbelloides (Douglas, 1829) - N British Columbia through C Alberta, C Saskatchewan, Manitoba and Ontario to Quebec.

B. u. labradorensis Quellet, 1990 - Labrador Peninsula.

B. u. sabini (Douglas, 1829) - Pacific coast from SW British Columbia to NW California

B. u. brunneus Conover, 1935 - Vancouver I.

B. u. castanea Aldrich & Friedmann, 1943 - Olympic Peninsula.

B. u. affinis Aldrich & Friedmann, 1943 - inland British Columbia S to C Oregon.

B. u. phala Aldrich & Friedmann, 1943 - SE British Columbia to E Oregon and SC Idaho.

B. u. incana Aldrich & Friedmann, 1943 - SE Idaho and W Wyoming S to C Utah.

B. u. mediana Todd, 1940 - Minnesota and S Wisconsin.

B. u. togata (Linnaeus, 1766) - S Ontario and S Quebec S to N Wisconsin, C Michigan and C New York.

B. u. thayeri Bangs, 1912 - Nova Scotia.

B. u. umbellus (Linnaeus, 1766) - C New York and C Massachusetts S to E Pennsylvania and New Jersey.

B. u. monticola Todd, 1940 - S Michigan, Ohio and Pennsylvania, through Appalachian Mts to N Georgia.

Descriptive notes. 43-48 cm; male c. 600-650 g, female c. 500-590 g. Relatively large grouse, with short crest, fan-shaped tail with highly distinctive dark subterminal band, and erectile black ruffs on sides of neck. Very cryptic plumage, with two colour morphs, grey and brown, and intermediates; grey morph commoner in N areas, brown in S; small orange-red combs, more developed in spring. Female very similar, but combs not developed, tail shorter and with incomplete dark band, and fewer white spots on rump. Immature retains two outer, more pointed juvenile primaries. Juvenile like adult female, but barred tail lacks subterminal band; more mottling on primaries.

Habitat. High diversity of woodland types in extensive range, from typical boreal forest to Pacific coast rain forest, and relatively dry deciduous forest, but always with some deciduous trees, especially aspens (*Populus tremuloides*, *P. grandidentata*), range of which largely coincides with that of present species. Earlier successional stages generally preferred, as are scattered openings with herbaceous plants, so logging and fires tend to improve habitat quality. A small percentage of coniferous trees can provide valuable cover during winter.

Food and Feeding. During winter, largely buds and twigs of trees, especially in regions of continuous snow cover. Male flower buds of aspens seem to be most important winter resource; other plants taken include *Betula*, *Salix*, *Alnus*, *Corylus*, *Prunus*, *Acer* and *Cornus*, depending on availability. In New England, even turns to apple orchards. After winter, diet diversifies with access to leaves and flowers of ground vegetation, but buds and catkins of trees often remain important. During summer, berries and other fruits (*Fragaria*, *Rubus*, *Prunus*, *Amelanchier*, etc.) become significant, and small quantities of insects also taken. Arthropods are basic food for chicks during first 1-2 weeks, especially ants, also sawflies, ichneumon flies, beetles, spiders, grasshoppers and caterpillars. Autumn food includes variety of fruiting shrubs (*Sorbus*, *Cornus*, *Viburnum*), leaves, acorns, mushrooms and increasing proportions of buds and catkins.

Breeding. Laying mostly in May. Promiscuous; males dispersed. Nest is bowl formed in leaves on forest floor, without lining, usually at base of tree, stump, boulder or large log, in fairly open situation. Lays 10-12 eggs (6-15); incubation 23-24 days; downy young have black on head restricted to little more than two elongated ear patches reaching the eyes; chicks capable of flight at 10-12 days; first primary shed at c. 14 days. In Alberta, 80% of clutches hatched, and 37-51% of chicks survived at least 12 weeks, in Minnesota, 32% of nests were destroyed before hatching and about 40% of chicks survived until mid-Aug. Sexual maturity at one year old. Annual adult survival rate 47% in males; mean longevity after first autumn 1.25 years; maximum known survival in marked birds almost 4 years.

Movements. Highly sedentary. Short range juvenile dispersal in autumn, with females moving farther; in Minnesota, females move 3-4 times more than males, maximum c. 17 km.

Status and Conservation. Not globally threatened. Widespread and fairly common throughout most of original range. Some range contractions in past almost compensated for by successful restocking and even introductions into new areas (e.g. Newfoundland, Nevada). Density varies widely between habitats and especially between years, with fivefold to tenfold fluctuations, roughly in 10 year cycles; up to 50+ breeding birds/km². Extensively hunted; annual bags in late 1970's estimated at c. 6,000,000 birds, but in most areas hunting is probably at sustainable levels. Increasing commercial importance of aspens and some recent forestry management practices seem highly beneficial.

Genus *CENTROCERCUS* Swainson, 1832

14. Sage Grouse

Centrocercus urophasianus

French: Tétrás des armoises German: Beifuhuhn Spanish: Gallo de las Artemisas
Other common names: Sage Hen/Chicken

Taxonomy. *Tetrao urophasianus* Bonaparte, 1827, "North-western countries beyond the Mississippi especially on the Missouri"

Known to have hybridized occasionally with *Tympanuchus phasianellus*, and once with *Dendragapus obscurus*. Populations of NW, from Washington to Oregon, sometimes awarded separate race, *phaios*. Monotypic.

Distribution. W North America, from C Washington, SE Alberta, SW Saskatchewan and SW North Dakota, S to E California, Nevada, Utah and W Colorado. Formerly also in extreme S British Columbia, N New Mexico and extreme NW Arizona.

Descriptive notes. Male 60-70 cm, female 48-58 cm, male c. 2300-3200 g, female c. 1350-1750 g. Greyish brown variegated plumage, with distinctive black belly and long, stiff, pointed tail feathers. Male considerably larger, has black in throat and upper neck, separated by V-shaped white line; large white ruff on breast, large greenish cervical sacs, and relatively inconspicuous yellow eyecombs; white underwing-coverts. Immature like adult female, but paler, with outer primaries more pointed and mottled. Juvenile shows shaft streaks on upperparts and tail feathers.

Habitat. More or less arid grassland with sagebrush (*Artemisia*, mainly *A. tridentata*), in foothills and plains. Winter distribution and relative abundance conditioned by availability of sagebrush above snow. Display grounds tend to be in relatively open cover. Most nests are placed under sage plants, taller ones being preferred. Young broods occur in areas with lower plant density and crown cover.

Food and Feeding. Sagebrush constitutes 62-77% of adult diet overall in year, and almost 100% in winter. Herbaceous legumes and weeds (*Taraxacum*, *Tragopogon*, *Trifolium*, *Astragalus*, *Lactuca*, etc.) also important.

mainly during summer and for juveniles. In some areas species feeds on cultivated legumes, e.g. alfalfa and clover. Adults take small amounts of insects (in one study 9% in summer, 2% both in spring and in autumn); during early life, chicks rely on ants, beetles, weevils and grasshoppers, which represent up to 75% of food during 1st week.

Breeding. Laying mostly Apr-May. Promiscuous; males form leks. Nest is shallow depression, usually poorly lined with grass and sage leaves, sometimes without any lining at all, usually under sagebrush plants 25-50 cm tall. Lays 7-8 eggs (up to 15); incubation 25-27 days; downy young have characteristic mottled combination of black, brown, buff and white, but no striping; fly at 1-2 weeks; first primary shed at 24 days. Clutches that hatch, 24-60% in different studies, apparently not many replacement clutches laid; average brood size changed in one study from 5-6 in Jun to 2-3 by Aug. Sexual maturity at 1 year, but probably few males mate until at least 2. Annual adult survival rate 48% in males, 40% in females; one female recovered at 8 years old.

Movements. Mostly sedentary, but in mountainous areas altitudinal movements take place between winter and spring-summer grounds; in Idaho covering up to 80-160 km. Autumn movements gradual, probably depending on snow conditions. Adult males arrive first at display areas, as soon as snow melts. Limited amount of daily movement.

Status and Conservation. Not globally threatened. Still found in most of original range, although some peripheral shrinking has resulted in extinctions in British Columbia and New Mexico, and locally in California. Population levels apparently lower during 1940's. In 1952 total population estimated at c. 150,000 birds, spread over c. 54,000 km² of preferred habitat. During late 1970's, annual hunting bags totalled c. 280,000 birds, including 94,000 in Wyoming, 93,000 in Idaho, 66,000 in Montana, 28,000 in Utah, 18,000 in Nevada, and 12,000 in Colorado; levels apparently not excessive in general. Major threats, given specialized needs for sage plains, are continuous extension of irrigated farmland and elimination of sagebrush by mechanical or chemical means to improve grazing conditions.

Bibliography. Autenrieth (1969, 1981), Autenrieth *et al.* (1982), Barber (1991), Beck (1975, 1977), Beck & Braun (1978), Berry & Eng (1985), Blake (1970), Blus *et al.* (1989), Boyce (1990), Boyce & Tate (1979), Braun *et al.* (1977), Carr (1967), Connelly (1982, 1983), Connelly *et al.* (1988, 1991), Crawford & Lutz (1985), Dalke *et al.* (1960, 1963), Dunn & Braun (1985, 1986), Ellis, K.L. *et al.* (1989), Emmons (1980), Emmons & Braun (1984), Eng (1963), Eng & Schladweiler (1972), Gate (1985), Gibson (1990, 1992), Gibson & Bachmen (1992), Gibson & Bradbury (1986), Gibson *et al.* (1991), Gill (1965), Hartzler (1972, 1974), Hartzler & Jenni (1988), Hupp & Braun (1989a, 1989b, 1991), Johnson & Boyce (1990), Klebenow (1968, 1969), Klebenow & Gray (1968), Klotz & Lindzey (1989, 1990), Lumsden (1968), Martin (1970), Patterson (1952), Petersen (1980), Peterson (1970), Rasmussen & Griner (1938), Rensel & White (1988), Rich (1985, 1993), Ridgway & Friedmann (1946), Rogers (1964), Schlatterer (1968b), Schneegas (1967), Scott (1942), Spurrier *et al.* (1990), Terres (1980), Vehrencamp *et al.* (1989), Wakkinen *et al.* (1992), Wallestad (1971, 1975), Wallestad & Pyrah (1974), Wallestad & Schladweiler (1974), Welch *et al.* (1988), Wiley (1973, 1978).

Genus *TYMPANUCHUS* Gloger, 1842

15. Sharp-tailed Grouse

Tympanuchus phasianellus

French: Tétrás à queue fine **German:** Schweifhuhn **Spanish:** Gallo de las Praderas Rabudo

Taxonomy. *Tetrao Phasianellus* Linnaeus, 1758, Canada = Hudson Bay. Formerly placed in genus *Pedioecetes*. Hybridizes extensively with *Tympanuchus cupido* where ranges overlap, with both hybrids and backcrosses apparently fertile; hybrids can constitute 0.3-1.2% of combined population in Nebraska, and up to 5-25% on Manitoulin I, Ontario, where contact of these species is recent. Six subspecies currently recognized.

Subspecies and Distribution.

T. p. caurus (Friedmann, 1943) - Alaska to S Yukon, N British Columbia and N Alberta.
T. p. kennicottii (Suckley, 1861) - Mackenzie.
T. p. phasianellus (Linnaeus, 1758) - N Manitoba, N Ontario and WC Quebec.
T. p. campestris (Ridgway, 1884) - S Manitoba and S Ontario to Minnesota, Wisconsin and Michigan; formerly to N Illinois.
T. p. jamei (Lincoln, 1917) - NC Alberta and C Saskatchewan S to Wyoming and Nebraska; formerly to Kansas.
T. p. columbianus (Ord, 1815) - NC British Columbia S to N Utah and W Colorado; formerly to N New Mexico (perhaps *jamei*).

Descriptive notes. 40-48 cm; male c. 950 g, female c. 815 g. Pointed tail characteristic, with central pair of rectrices extending far beyond the others; pure white undertail-coverts; small erectile crest; inconspicuous yellow eyecomb; pinkish to purple cervical sacs. Similar to prairie-chickens, but with paler underparts speckled, not barred. Female and immature very much alike, immature

showing pointed and faded outer two primaries. Juvenile has whitish throat and shorter tail. N birds darker.

Habitat. Wide range of open environments, from grassland and sagebrush semi-desert to relatively dense successional stages of deciduous, mixed or boreal coniferous forests. Preferred amount of tree and bush cover varies with different regions and races; in Wisconsin, most abundant in areas 25-50% covered with wooded vegetation, but in North Dakota minimum of 5% brush cover is tolerable. Availability of food sources, often related to snow depth, important for winter habitat; in some areas presence of trees like birches and aspens may be required. Display grounds usually in rather open, elevated sites, where visibility is good. Brushy or tall grass areas may be important in prairies and plains for resting, nesting and brooding, but in forested areas some form of opening seems essential for feeding. Cultivated fields commonly used for feeding and even for displaying, but apparently not often for nesting.

Food and Feeding. Rather adaptable. During winter, if snow conditions oblige tree-feeding on buds and catkins, primary plant food changes to paper birch (*Betula papyrifera*) in Ontario, Michigan and Wisconsin, to willow (*Salix*) in North Dakota, and to maple (*Acer*) and choke-cherry (*Prunus virginiana*) in Utah. Other genera of plants that are commonly eaten in winter are *Populus*, *Corylus*, *Sorbus*, *Amelanchier*, *Juniperus*, etc. During spring and summer herbaceous plants, including cultivated cereals, clover and alfalfa, make up most of the diet; flowers (*Taraxacum*, *Ranunculus*) also of some importance. Insects (e.g. grasshoppers) may also be important during summer, but apparently less so than in other *Tympanuchus*. Autumn food is most variable and includes grain in cultivated areas (wheat, corn, barley, millet, rye, etc.), as well as seeds, leaves, berries and other fruits.

Breeding. Laying Apr-Jun. Promiscuous; males form leks. Nest is slight depression on ground, lined with grass, leaves and some feathers, usually concealed by tuft of tall grass or under bush, in a variety of sites. Lays c. 12 eggs (5-17); incubation 23-24 days; downy young resembles that

of *T. cupido*, but is purer, paler yellowish, lacking rusty tints; chicks capable of flight at 10 days. Clutches that hatch, 40% and 55% in two different studies; brood size reduced from 8-7 to 4-6 young in another study. First breeding at 1 year old. Annual survival rate 40%; average life span estimated at 1.5 years for females and 1.6 years for males; one ringed bird observed at 7.5 years.

Movements. Largely sedentary, with some movements from grassland areas to woody cover in winter. Before advent of agriculture, with changes in prairie habitat and availability of grain, more marked seasonal movements apparently occurred. In Wisconsin, 81% of recoveries within 3-2 km of ringing place. Females and juveniles disperse more; maximum distance recorded c. 150 km in juvenile female. Limited amount of daily movement.

Status and Conservation. Not globally threatened. Still relatively common and widespread in Canada, but range has contracted considerably in S & W; now extinct in 8 states of USA (California, Oregon, Nevada, New Mexico, Oklahoma, Kansas, Iowa and Illinois); occupies less than 50% of original area in other 9 states. Most threatened race is *columbianus*, now with c. 80% of total population of 60,000-170,000 birds restricted to British Columbia, where considered "of special concern". Total population of *campestris* estimated at 600,000-2,000,000 birds; of *jamei* at 600,000-3,000,000 birds. Commonly hunted, and bags amounted to c. 700,000 birds/year during late 1970's (c. 440,000 in USA, 260,000 in Canada). Main problems derive from habitat change into modern cropland, or, in other areas, into woodland, through forest succession or plantation of conifers. Controlled burning useful in maintaining conditions of lekking grounds.

16. Greater Prairie-chicken

Tympanuchus cupido

French: Tétrás des prairies **German:** Präriehuhn **Spanish:** Gallo de las Praderas Grande
Other common names: Prairie/Pinnated Grouse

Taxonomy. *Tetrao Cupido* Linnaeus, 1758, Virginia.

Often considered conspecific with *T. pallidicinctus*. Hybridizes extensively with *T. phasianellus* in areas of overlap. Nominative *cupido* of E USA, from Massachusetts S to Maryland, extinct since 1932. Two extant subspecies recognized.

Subspecies and Distribution.

T. c. pinnatus (Brewster, 1885) - mainly from Dakotas S to Nebraska, Kansas and Missouri; formerly from C Alberta and SE Ontario S to Arkansas.
T. c. atwateri Bendire, 1893 - coastal areas of Texas and (formerly) SW Louisiana.

Descriptive notes. 41-47 cm; male c. 990 g, female c. 770 g; *atwateri* slightly smaller. Brown and extensively barred, on both upperparts and underparts; blackish tail short and rounded; elongated feathers on sides of neck, "pinnae", c. 70 mm long in *pinnatus*, erected during courtship; golden yellow cervical sacs; yellow to orange eyecombs. Female much alike, but tail barred, "pinnae" shorter (c. 38 mm in *pinnatus*), and cervical sacs and combs considerably smaller and paler. Immature also similar, but two outer primaries pointed. Juvenile shows prominent shaft streaks on scapulars.

Habitat. Originally in native prairies intermixed with oak (*Quercus*) woodlands: race *cupido* in scrub oak (*Q. ilicifolia*) mixed with fire-created grasslands or blueberry (*Vaccinium*) barrens, associated with sandy soils; *atwateri* in sandy coastal plains; *pinnatus* in prairie openings in oak woodlands, in oak savannas, and in oak grassy forests extending into tall grass prairie. Marked changes took place with advent of agriculture, so nowadays main habitat is prairie intermixed with croplands. Areas of native vegetation required for roosting and breeding; for displaying, males select sites with short grass, usually on elevated ground. Most nests are in open, grassy habitats, e.g. ungrazed meadows or hayfields.

Food and Feeding. Transformation of original habitat into croplands brought important changes. Presently, cultivated grains (mainly corn and sorghum, also wheat, rye, oats and barley) are primary winter food in many areas, their importance decreasing with latitude (90% in North Dakota, 10-50% in Oklahoma, 9% in Texas). Acorns (*Quercus*) may have been of major importance in past, especially during snowy periods. Leaves, seeds and buds of a variety of plants are taken throughout year; also insects, mainly grasshoppers, which can amount to 30% during summer and are very important for chicks and juveniles. Species forages mostly in early morning and evening, during winter in two periods of c. 80 minutes each.

Breeding. Laying mid-Apr to early Jun (*pinnatus*); late Mar to early Apr (*atwateri*). Promiscuous; males form leks. Nest is bowl-like scrape, lined with feathers, dry grass, leaves, twigs and similar material, among thick grass cover. Lays 8-13 eggs (5-17); incubation 23-25 days; downy young have three black spots on top of head and one on forehead, and irregular small black marks over upperparts; some primaries already present at hatching, first one shed at c. 28 days. Clutches that hatch average 44% in *pinnatus*, 32% in *atwateri*; replacement clutches are usual; average brood size reduced in one study from 8.0 to 6.6 young. Sexual maturity at 1 year, but few yearling males mate. Annual adult survival rate 45% in males, 49% in females; one ringed bird observed at 8 years old.

Movements. Mostly sedentary; some birds, especially females and juveniles, may move 12-170 km between wintering and breeding areas, without any definite direction. As in *T. phasianellus*, in past movements may have been longer on average.

Status and Conservation. Not globally threatened. Despite conservation efforts, race *cupido* became extinct in 1932, having been confined to Martha's Vineyard I, Massachusetts, since c. 1870; market hunting and poaching thought to have played important role in decline. Race *atwateri* included in 1978/79 Red Data Book, classed as Rare; extinct in Louisiana in 1919; the remaining Texas population numbered c. 8000 birds in 1937, c. 2000 in 1970, c. 1500 in 1980, and under 1000 at present; only small part of population found in reserves. More widespread race *pinnatus* initially benefited by limited amount of agriculture and so greatly increased in numbers and range

by end of 19th century, but sharp declines followed further agricultural development, and now extirpated or endangered in 15 states and provinces; during the last 25 years has further decreased in 7 states and increased in just 2; total autumn population was estimated at c. 500,000 birds in 1979/80, about half the 1968/69 figure; largest remaining populations are in Kansas, Nebraska and South Dakota. Historical densities may have approached 2.5 birds/ha in optimum habitat. Still hunted in several states, with annual bags of c. 84,000 birds during late 1960's and c. 61,000 in late 1970's. Besides habitat alteration due to intensification of agriculture, other negative factors include excessive overgrazing in some areas and the invasion of woody plants in others; also pesticide use, reducing insect supply for chicks. Conservation measures now in progress in many areas, including establishment of reserves, reintroductions and restockings (not yet in Canada), control of predators, removal of competing introduced Ring-necked Pheasants (*Phasianus colchicus*) and especially habitat improvement through prescribed burning, manipulation of grazing pressure and provision of thick vegetation for protective cover.

17. Lesser Prairie-chicken

Tympanuchus pallidicinctus

French: Tétraz pâle **German:** Kleines Präriehuhn **Spanish:** Gallo de las Praderas Chico
Other common names: Lesser Prairie Grouse, Lesser Pinnated Grouse

Taxonomy: *Cupidonia cupido* var. *pallidicincta* Ridgway, 1873, prairies of Texas near lat. 32° N. Frequently considered a race of *T. cupido*. Monotypic.

Distribution. SE Colorado, SW Kansas, Oklahoma, E New Mexico and NW Texas.

Descriptive notes. 38–41 cm; male c. 790 g, female c. 700 g. Tail blackish in male, barred in female. Very similar to *T. cupido*, but smaller, paler, less heavily barred below and with cervical sacs orange-red, rather than yellow. Immature and juvenile similar to those of *T. cupido*.

Habitat. Arid grasslands with interspersed dwarf oaks and shrubs. Originally in two main plant communities associated with sandy soils: sand sage-sand bluestem (*Artemisia filifolia*-*Andropogon*

hallii); and shin oak-sand bluestem (*Quercus havardii*-*A. hallii*). During winter, grass cover is used for all activities, but roosting also takes place in shrubby areas, and feeding in sites with oaks (for acorns). Display grounds appear in areas with fairly short grass, on ridges or other elevations, but in valley meadows if ridges have tall dense sagebrush. Species nests among low shrubs or between grass clumps; broods move to heavier cover, e.g. oak motts or sagebrush.

Food and Feeding. Similar to *T. cupido*, but with much higher percentage of insects, e.g. in Oklahoma, yearly volume of insects 41.8-

48.6% for present species, as opposed to 8.2-20.8% for *T. cupido*). During summer, insects are main food even for adults. Cultivated plants, such as sunflower and sorghum, sometimes important winter food, especially during snowy periods. In New Mexico, shin oak is main food resource throughout year.

Breeding. Laying Apr-May. Promiscuous; males form leks. Nest is hollow on ground, amongst long grass cover, primarily of bluestem. Lays average 11 eggs (6-14); incubation c. 24 days; downy young nearly identical to those of *T. cupido*. Clutches that hatch, c. 28% in New Mexico (less in areas of lower vegetation). Sexual maturity at 1 year old. Annual survival rate 32% for males in one study.

Movements. Largely sedentary. In Oklahoma, 79% recoveries within 3.2 km from ringing place 97% within 6.4 km, while maximum distance recorded was 16 km; juveniles and females tend to move farther.

Status and Conservation. Not globally threatened. Considered threatened by US Fish and Wildlife Service (1973). Like *T. cupido pinnatus*, present species increased temporarily with advent of agriculture, expanding northwards, but during 20th century has also experienced a major long-term decline. Total population amounted to c. 50,000 birds in autumn 1979, with c. 7500 in Oklahoma, 11,000-18,000 in Texas, 17,000-18,000 in Kansas, and 10,000 in New Mexico; these spread over c. 27,000 km², less than 10% of original range. Now apparently stable, with only local declines. Densities in favourable habitat can reach 4-12 males/km², but average 2.8 in Oklahoma. During late 1970's, c. 5700 birds killed annually by hunters. Spread of agriculture into areas of short-grass prairie, facilitated by deep-water wells and center-pivot irrigation equipment, is major threat; in Kansas, caused habitat to diminish during 1970's at annual rates of 1.5-6%. Other problems could derive from local overgrazing and the invasion of steppe by woody vegetation.

Class AVES
Order GALLIFORMES
Suborder PHASIANI
Family ODONTOPHORIDAE
(NEW WORLD QUAILS)

- Fairly small terrestrial birds with compact body, strong legs, and short wings.
- 17-37 cm.

- Neotropical and Nearctic Regions.
- Tropical, subtropical and temperate forests, forest edge, savanna and agricultural land, from sea-level to 3300 m.
- 9 genera, 32 species, 139 taxa.
- 2 species threatened; none extinct since 1600.

Systematics

The New World quails are found primarily in the Neotropical Region and in the southern part of the Nearctic Region. The earliest fossil evidence is of a quail-like specimen found in Saskatchewan, Canada, dating to the Lower Oligocene some 37 million years ago, while there are also more recent fossils from the Miocene, Pliocene and Pleistocene. The earliest fossils of modern genera include a *Cyrtonyx* from the Middle Miocene in Nebraska (USA), about 16 million years ago, a possible *Lophortyx* (*Callipepla*) from the Middle Pliocene in Oregon, about 6 million years ago, and a *Colinus* from the Upper Pliocene of Kansas, 1.5-3.5 million years ago.

The taxonomic status of the family, and also of the genera and species within the family, has been debated for many years. The family is often considered a subfamily of Phasianidae, and thus it is grouped at various taxonomic levels alongside the Old World quails, partridges, francolins, and pheasants. However, DNA-DNA hybridization evidence suggests that the New World quails are not closely related to Old World quails, turkeys or grouse, indicating an early divergence in South America during its isolation from North America. The divergence of the New World quails is variously estimated to have occurred 63 or 35 million years ago, with DNA-DNA hybridization supporting the earlier of these dates. Further evidence in favour of family status for the New World quails comes from the fact that they are not known to have hybridized with any other members of Galliformes.

The presence of the most generalized species and the rich number of genera from southern Mexico and Guatemala suggest early radiation of the family from that region. Three groups of genera have been identified, with *Dendrortyx* being the earliest representative. The genera predominantly adapted to the forest, *Odontophorus*, *Rhynchortyx*, *Dactylortyx* and *Cyrtonyx*, are found in Central and South America, whereas the genera adapted to forest edge, *Colinus*, *Callipepla*, *Oreortyx* and *Philortyx*, are found primarily in North and Central America. This division into groups on habitat use is additionally supported by the pelvic structure.

Amongst the genera of New World quails, *Callipepla* and *Lophortyx* have often been classified apart, but nowadays the two forms are most commonly united in *Callipepla*, as the

differences seem too slight to merit generic separation. R. J. Gutiérrez and others, using starch gel electrophoresis and fossil calibration, suggest, for the North American genera, the earliest radiation of *Oreortyx* some 12.6 million years ago, followed by *Colinus* 7 million years ago, and most recently by *Callipepla* 2.8 million years ago. They also suggest that *Dendrortyx* and *Odontophorus* diverged at least 16 million years ago.

The classification of species within genera has also varied greatly, and this issue is still very far from being settled. Of the nine genera in the family, *Odontophorus* has the greatest number of species, with a total of 15. However, there are two groups of *Odontophorus* wood-quails found in the northern Andes, which constitute a rusty-breasted complex of four species and a black-throated complex of five species; the members of these groups might actually turn out to represent smaller numbers of species. Several species in the genera *Callipepla*, *Colinus* and *Cyrtonyx* have also been merged by various authorities. A large number of natural hybrids have been reported among different species of *Callipepla*, and also with the Northern Bobwhite (*Colinus virginianus*). Although North American species have been analysed using a number of techniques, many South American species are presently classified with very little supporting evidence.

Morphological Aspects

The external appearance of the New World quails is very much like that of the Old World quails and partridges. In Latin America they are often lumped with the tinamous under the vernacular Spanish name "perdices". With their similar appearance, habitat and habits it is easy to mistake several species of these families where they occur together, even though they are not closely related.

The size range is not nearly as variable as that found in some of the other galliform families. The smallest species are the bobwhites (*Colinus*), the Barred Quail (*Philortyx fasciatus*), and the Tawny-faced Quail (*Rhynchortyx cinctus*), which are all slightly smaller than the average Northern Bobwhite. The largest species is the Long-tailed Tree-quail (*Dendrortyx macroura*), which is the size of a Grey Partridge (*Perdix perdix*).

The New World quails are small, compact birds, most of which have striking plumage, mainly in grey, black, white, buff, brown and reddish. Many species in the family have crests or other ornamental features on the head, such as the unusual teardrop-shaped plume found in Gambel's Quail and the California Quail (*Callipepla californica*). These adornments are normally more developed in the male, and it is believed that they play an important part in breeding displays, as, in many species, does the sharply contrasted pattern of the head and throat. This individual also illustrates the ease with which New World quails can perch on the sharp spikes of cacti. These plants are common in the xeric habitats to which most of the North American species are so well adapted.

[*Callipepla gambelii*,
Sonoran Desert, Arizona,
USA.
Photo: John Cancalosi/
DRK]

Most species of New World quail show marked sexual dimorphism in their plumage. Females lack the more distinctive patterns, or at least these are much less conspicuous and differentiated. The crest, rounded and particularly prominent on the back of the head in the Montezuma Quail, is also normally less pronounced in the female.

[*Cyrtonyx montezumae mearnsi*, Davis Mountains, Texas, USA. Photo: C. C. Lockwood/Bruce Coleman]

Almost all species are compactly built with a short neck, wings and tail. The exceptions are the three tree-quails (*Dendrortyx*), which have rather long tails. Several species have some form of ornamentation on the head, ranging from small crests, as commonly seen in the wood-quails (*Odontophorus*), to the long feathers in the shape of a teardrop found in California Quail (*Callipepla californica*), and the "spike" sported by the Mountain Quail (*Oreortyx pictus*). The bill is serrated, and, typical of seed-eaters, is short, stout and slightly decurved; it is especially short and stout in the wood-quails. In most species bill colour is black or grey, but two of the tree-quails have handsome red bills.

The ground-dwelling habits of most species are revealed by their short, powerful legs, as these are birds well designed for terrestrial locomotion. The tarsus is unfeathered and, unlike many of the Old World galliforms, none of these quails have tarsal spurs, in either sex. All species have three front toes and a raised hallux, or hind toe. The toes of many of the tropical species are especially long, which may be an adaptation for digging into the soil for roots and insects, rather than scratching in the litter for seeds, the norm for many of the more temperate species.

Although many species are powerful fliers over short distances, most apparently prefer to run rather than fly, when alarmed. When they do take to the air, they often start with a very steep take-off, but even then they usually fly only very short distances. As in other groups of Galliformes, the wingbeats are rapid, with alternating glides and little variation in direction. As most species live in groups, when alarmed birds will often explode from the ground in all directions, presenting a confusing spectacle to any potential predator.

Plumage colour ranges from very dull to a rather subtle spectacular. Most species have rather dull coloration and mottling, which is related to their shy, skulking behaviour. However, when viewed at close range, many species have striking red or purple eye-rings, or contrasting rows of white "teardrops" or spots on the breast. The Montezuma Quail (*Cyrtonyx montezumae*) exemplifies this contrast with a black base colour to the breast and belly covered extensively with brilliant white spots. Many species have strongly contrasted coloration on the face and throat, especially in males, and this probably performs functions in sexual displays.

There is some sexual dimorphism in plumage in almost all the species of this family. None, however, are as dramatic as the differences seen in several other Galliformes, notably some pheasants (see page 440). Typical sexual differences include the male being slightly larger, with slightly brighter plumage. Often, when a crest or some other form of ornamentation is present, it is larger in the male. A contrasting coloration in the region of the face and throat is often a dramatic black or white

The general appearance of the Odontophoridae is very similar to that of the Old World partridges, but there are some striking differences. One of these is the stronger, very pointed bill, which has more or less serrated edges, as can be seen in this Mountain Quail. This species is unique in the form of its crest, which consists of two immensely long, thin head plumes that often appear to be joined together in one.

[*Oreortyx pictus*, Western Mountains, USA. Photo: Erwin and Peggy Bauer/Bruce Coleman]

Many New World quails, such as the Northern Bobwhite, can fly quite strongly, with rapid wingbeats, but only for short distances. Unlike some Old World quails, no member of the Odontophoridae performs true migrations, but dispersive movements after breeding are typical, as are altitudinal movements in species which inhabit mountainous areas.

[*Colinus virginianus mexicanus*, Ohio, USA.

in the male, but a much duller buff or mottled brown in the female.

Plumage development is fairly consistent among all the different groups of galliforms. Feather tracts are similar and the presence of insulating aftershafts on contour feathers is common. Moulting occurs in chicks at a very young age, when they are passing through a period of rapid development (see Breeding). Among well studied species, first-year birds are often distinguishable from older ones by the tendency for the outer two primaries on each wing to be pointed and frayed, as these two outermost flight-feathers are not moulted in the first year like all the others. The number of primaries is consistently ten, but the number of secondaries varies from 14 to 16, although

these feathers grade into the scapulars, so that it is not always easy to make a clear separation.

Common to this group and other Galliformes is the presence of a blind sac in the cloaca called the bursa Fabricius. This structure, located on the dorsal wall of the cloaca, is larger in immature birds and decreases as the animal matures. It functions in antibody production, and has been used for ageing in a number of galliform species.

Habitat

The New World quails now inhabit a variety of ecosystems ranging from tropical rain forests to desert scrub. The group shows a strong preference for subtropical and mild temperate climates, and there is very limited representation in the colder temperate climates of North America. The Northern Bobwhite and the Mountain Quail range into cold climates, but even they can not tolerate the low temperatures endured by many of the Old World Phasianidae or the grouse (Tetraonidae).

The greatest diversity of species is associated with Neotropical forests. The wood-quails (*Odontophorus*), which represent almost half of the species in the family, are found in tropical rain forest, subtropical forest, montane and cloud forests, and deciduous forest. Most of the species in this genus are found in thick underbrush in these habitats, although a number of species can be found at forest edges and in second growth. Several species have been reported to use coffee plantations, but they appear to use coffee grown under bananas or other trees, rather than open fields of coffee.

The species found in North America are the best adapted to xeric conditions and, not surprisingly, to a temperate climate. Most still show their forest edge affinities, but several species are found in desert scrub and even in agricultural habitats. The bobwhites (*Colinus*) have also exploited more xeric ecosystems in Central America and northern South America. The Northern Bobwhite is one of the species that has adapted most fully to the temperate zone, where it utilizes both forest and open habitats. In the south-eastern USA, some of the densest populations are found in open pine woodlands with a well developed under-

New World quails use a very wide range of habitats. Most species inhabit various kinds of woodland, but some are well adapted to agricultural areas and even arid or semi-arid zones, as is the case of the Scaled Quail. The common name of this species comes from the dark edges to the feathers of the breast and mantle, which produce a shingled or scaly effect. Another distinctive characteristic of the species is its conspicuous white-tipped crest.

[*Callipepla squamata pallida*, Arizona, USA.

Photo: John Shaw/NHPA]

Unlike the North American species of the family, which frequent open areas and even markedly arid zones, only one of the South American species, the Crested Bobwhite, favours this type of habitat. It is found in and around thickets, savanna, grassland, embankments, roadsides and cultivated land, but it does not enter the forest interior, although it can be found in the margins. All the other South American species are predominantly, or exclusively, forest dwellers.

[*Colinus cristatus parvicristatus*, La Ye, Apure, Venezuela. Photo: A. Greensmith/Ardea]

storey of wiregrass (*Aristida stricta*). In the Midwest, populations are frequently associated with grassland and intensive agricultural ecosystems.

An interesting habitat adaptation is found in the Montezuma Quail and the Ocellated Quail (*Cyrtonyx ocellatus*). Both of these species are found in open pine or oak woodlands, but both depend heavily on the bulbs and tubers of a number of different types of herbaceous plants, most notably wood sorrels (*Oxalis*).

General Habits

The New World quails are shy and elusive, and they invariably prefer to hide and crouch in the vegetation, when alarmed, rather than flying away. If they do move off, many species are more likely to slip away unnoticed than to flush, but when a flock is flushed, take-off is often explosive, with birds flying off in many directions.

These are highly gregarious species, which regularly live in groups. After breeding, birds often move about in family groups, which consist of the two adults and their offspring. However, outside the breeding season, a number of temperate species, such as the California Quail, will congregate in large flocks, which can number up to 1000 individuals, when the conditions are suitable.

Most species are apparently diurnal, and are thought to spend the majority of their time on the ground. Indeed, all of the North American species live on the ground, and they generally roost on the ground at night. The tree-quails (*Dendrocygna*) of Central America are probably the most arboreal species, and at night they roost in tall trees; nevertheless, they are reported to feed mainly on the ground. Tree-roosting has also been reported for the Barred Quail, although this is essentially a species that occupies scrub. There are some accounts of Venezuelan Wood-quails (*Odontophorus columbianus*) roosting in rows along palm fronds, while it has also been claimed that the Chestnut Wood-quail (*Odontophorus hyperythrus*) roosts in trees. It seems that this habit might be more common in wood-quails than has been realized up to the present.

Voice

The rather primitive, poorly developed tracheal syrinx found in the Odontophoridae results in a rather simple vocal repertoire. However, despite this mechanical limitation, some species are reported to boast a fair number of distinct calls.

The Northern Bobwhite has a minimum of 19 distinct calls, and perhaps up to five others, whereas 10-14 different calls have been reported for the species of *Callipepla* found in the western USA. Most of the variation in types of call is related to the courtship behaviour of males, but other common calls in these species include various kinds of separation calls for regrouping, feeding calls and alarm calls. Among the bobwhites, calls are often a whistle-like "bob-white", whence the common name. In contrast, the *Callipepla* quails have calls resembling shrieks and chipping sounds, as well as some whistles. The calls of tree-quails consist of a loud hooting and grunting, which is often performed in chorus. Amongst the wood-quails, calls tend to be rolling and guttural, and in south-western Colombia rural people call the Chestnut Wood-quail "aguacero vientoado", meaning "rain with wind", a description of the sound of its call.

In the cases where information is available, calls are most often concentrated around dawn and dusk, and with greater frequency during the breeding season. Group calls are found in a number of species, and in the Venezuelan Wood-quail these often become raucous choruses, with up to nine birds in a group. It is interesting to note that duetting has been reported among pairs of Marbled Wood-quails (*Odontophorus gujanensis*). This behaviour might be found to be more widespread among the wood-quails, when other species have been more fully studied.

Food and Feeding

Most of the species in this family tend to be generalists and opportunists in terms of the food they take. The long lists of types of food consumed that are available for several of the better studied species are testament to this lack of specializa-

tion. Many of the Central and South American species are in great need of more detailed studies of their food requirements.

The majority of species that are mainly adapted to living in xeric areas are seed-eaters, but most of them will also consume green vegetation, tubers, buds and insects. The tree-quails of Central America also consume a diversity of foods, but they are more likely to feed in trees than other genera, even though they too are reported to feed mostly on the ground. The wood-quails are reported to feed on a diversity of food types, but they may consume more animal food and roots. The Montezuma and Ocellated Quails, in turn, depend heavily on tubers.

Virtually all of the species in which the feeding habits have been studied show an increase in the consumption of insect and animal foods during the breeding season. This diet pattern is reported in many other species of Galliformes, and is attributed to the need for food with higher protein value during breeding. Again, in these same species the chicks have also been found to require insects during their first few weeks after hatching, when their growth rate is fastest.

Foraging patterns are rather diverse, reflecting the variety of food types consumed. The species inhabiting xeric parts of the western USA tend to peck at food rather than scratch for it, although most species will also scratch in the litter for seeds. These species are also more likely to eat green vegetation and succulents in order to procure water, a common tendency of animals living in such dry conditions. However, some species, such as the California Quail, are associated with standing water during the dry season.

The Montezuma and Ocellated Quails and also the wood-quails, all species that regularly eat tubers and roots, have long, powerful legs and toes, which are well suited for excavating soil. These species often forage in rows, clearing long paths through the leaf litter of their forest habitats. Tell-tale signs of wood-quails during the dry season are the rustling of leaves and flying litter, as a line of birds clears a path along the forest floor; the cleared areas often run along the edges of surface roots or rocks.

Breeding

The breeding biology of most of the Neotropical species of New World quails is neither well studied nor well understood, and a good deal of the very limited information available is anecdotal. Much more research is required on the diversity of reproductive patterns in this interesting group. In this aspect, as in most others, the vast majority of what is known refers to the species found in the USA.

Most species are apparently monogamous, although there are indications that this might not necessarily be the case for some wood-quails. As is to be expected, those species inhabiting temperate areas tend to breed in spring and early summer, with laying mostly from about April onwards. The season is rather more variable in the tropics, but typically coincides with the local wet season.

Courtship displays in North American species incorporate a number of frontal and lateral postures by males. These can include the use of the brightly coloured throat or the crest, while the wings are often dropped or spread. "Tid-biting" (see page 458) is common, and calls are often used in conjunction with visual displays. Nonetheless, most of the courtship activities of the New World quails are not nearly as dramatic as many of their galliform relatives.

The nest is almost always made on the ground, and it usually consists simply of a shallow depression lined with vegetation. It is most often hidden from above by thick vegetation, but some of the wood-quails actually construct domed nests with a long tunnel entrance.

As in most of the Galliformes, clutch size is considerably larger than in most other groups of birds. Typical clutch size is about 10-15 eggs for bobwhites and other North American species, as well as their congeners, but 3-6 eggs might be more typical of the tree-quails and wood-quails of Central and South America. For a few well studied species, such as the Northern Bobwhite, there are records of intraspecific brood parasitism, with one or more females laying in another female's nest. It is

The flowers and sweet fruit of the saguaro constitute an important food source for those species, such as Gambel's Quail, that are found in the semi-deserts where this cactus thrives. However, the diet of this quail species is actually quite varied and includes seeds, flowers and fruits of many plants, as well as assorted grasses. In contrast, for the Gila Woodpecker (*Melanerpes uropygialis*), seen here in the background, the fruit of the saguaro, when available, is its main source of food.

[*Callipepla gambelii*.

Gohier/Ardea]

Northern Bobwhites generally form coveys, except early in the breeding season, when they are found in pairs. At the beginning of the summer the covey is made up of the family group, including both of the adults and the chicks. Other birds gradually join, from other coveys which have been decimated by predation or disease, or birds that have, for various reasons, become isolated. At the beginning of autumn, it is common for the coveys to begin to mingle, with many birds swapping covey affiliation in a process known as the "fall shuffle". Finally, in spring, the coveys disperse, as birds pair off in preparation for breeding.

[*Colinus virginianus*.

FLPA]

interesting to note the presence of brown or red spots on the mainly whitish eggs of many of the Neotropical species: because the breeding season of these species often coincides with the wet season, there is the potential for the leaching of colour onto the shells, and it seems that these spots are thus the result of staining by the vegetation or soil in the nest. The California Quail and Gambel's Quail (*Callipepla gambelii*) are both known to lay a second clutch on occasions.

The incubation period appears to vary widely among the different species, but it should be noted that in several cases where estimates are available for a particular species, the data have actually been collected from very few individual clutches. For the better known species, incubation ranges from 21-23 days in *Colinus* and *Callipepla*, to 25-26 days in *Cyrtonyx*. Among the poorly studied wood-quails, reports include estimates of 16-17 days for the Black-breasted Wood-quail (*Odontophorus leucolaemus*), 18-19 or 26-27 days for the Spotted-winged Wood-quail (*Odontophorus capueira*), 24-28 days for the Marbled Wood-quail, and 30 days for the Venezuelan Wood-quail.

Chicks are nidifugous, and, soon after hatching, wander off from the nest guarded by the female or both adults in a family group. At this stage, the chicks grow very rapidly, and the primaries and secondaries are acquired early on, so that the chicks of some species are capable of short flights at less than 14 days of age.

The amount of male parental care varies with the species. Male assistance during incubation has been reported in some cases, especially in the latter stages and around the time of hatching. As the breeding biology of more species becomes better known, so male assistance with the tasks of incubation and brood-rearing will undoubtedly be more commonly reported. In some of the wood-quails, there are reports of guarding behaviour near the nest by adults other than the parental pair, but this anecdotal information needs to be confirmed by more intensive studies.

The New World quails are generally species with short lives, high mortality, and high reproductive rates. Annual survival rates of the better studied species in the USA very rarely top 30%. Nesting success rates of 20-40% are commonly reported for the Northern Bobwhite, but adults are persistent reneesters. Brood mortality is often over 20%, and losses of even

30-50% are not uncommon, with the result that life expectancy is usually under one year. It is not surprising then that the productivity of these species is very high. There is a trend toward smaller clutch sizes in the forest-adapted species found in Central and South America; there are virtually no estimates of lifespan and mortality rates for those species, but with the much lower productivity rates, it would not be surprising if there were greater adult survivorship.

Movements

The major mode of movement for the species in this group is walking, and this is consistent with the idea that virtually all species would be considered sedentary. Home range is very small, typically under 40 hectares among the better studied species found in the USA.

Altitudinal migration has been reported in the Mountain Quail and it is suspected in the Spotted Wood-quail (*Odontophorus guttatus*), but there is no evidence of similar movements in other species. The most mobile species in this family are the Scaled Quail (*Callipepla squamata*), which has been known to move up to 100 km, and the Mountain Quail, with reported movements of over 50 km. However, these types of movement are probably exceptional, and the sort of distances more typical travelled by Scaled Quails are of less than two kilometres.

Relationship with Man

Like most of the other galliforms, the New World quails have a long history of association with man. This association has been both beneficial and detrimental at times, depending on the perceived value of the particular species and the land use practices.

Pre-Columbian cultures in North and South America utilized a number of different species of quails as food sources. In some of these cultures, there were periods when the potential for overexploitation existed. Alterations of habitat were at times liable to have a negative impact on some species, and at the same time positive effects on others. Mayan agriculture in

It appears that the Spot-winged Wood-quail is monogamous, at any rate in captivity. On the left of this photo is the characteristic nest of this species, a shelter built on the ground of dry leaves, with a side entrance and a substantial roof which prevents the white eggs from being seen from above. Also clearly visible here are the bright red eye-ring and the broad tawny orange supercilium, the most distinctive features of this species.

[*Odontophorus capueira*,
Brazil.

Photo: R. Seitre/Bios]

southern Mexico and northern Central America consisted of a mosaic of *milpas* in forest areas and raised bed agriculture in lowlands. This had the potential of increasing the populations and distribution of both the Northern Bobwhite and the Black-throated Bobwhite (*Colinus nigrogularis*), but it might equally have been detrimental to forest-dwelling quails. Very dense human populations in the region at the same time may well have taxed quail stocks.

In North America, native tribes in the east were known for using fire to alter the expansive forest ecosystems. The Northern Bobwhite no doubt benefited from these habitat alterations, but, nevertheless, evidence suggests that this species was not an important food item. In western North America, the California Quail was highly esteemed as a source of food by the native tribes, and the "top-knot" was used for decoration on clothing. It has been suggested that the population of California Quails on the island of Santa Catalina, off Los Angeles (USA), was originally introduced by local Indians, and certainly there is evidence of rural peoples in Latin America having kept several quail species as pets. One problem with our understanding of quail use throughout history is that even today there is little distinction made between the quails, tinamous and cracids of the region.

The combined factors of European settlement in the New World, fairly dramatic changes in the landscape, and interest in quails for sport and food have led to the distributions and populations of species that we find nowadays. The extensive logging and then reforestation of the eastern USA since the seventeenth century has had a dramatic impact on the distribution and populations of the Northern Bobwhite. This species was very important during the eras of settlement and hunting for markets, and it probably suffered periodically as a result of these pressures. Despite market hunting pressure, populations are thought to have increased generally in the USA until the middle to late nineteenth century, due to forest clearing; most of the population declines have, in fact, occurred during the latter half of the twentieth century. A similar pattern of population change has also been described for the California Quail. Both of these species and the other quails in the western USA are presently important in the business of hunting for sport, and in some areas extensive management is carried out for these species.

The early impacts of European settlers on other North American quails were probably considerably less significant, but they too were no doubt heavily harvested during settlement. Exploitation of quails in Latin America during and after European settlement probably paralleled the North American situation, but it is less well documented. Although many species of quails are considered eminently edible in Latin America, their small body size limits demand. It is interesting to note that in south-west Colombia the Crested Bobwhite (*Colinus cristatus*) is said to be "maldito" and should not be eaten; this translates to "cursed" or "damned", in reference to the Virgin Mary being frightened when she flushed a covey of Crested Bobwhites! There is some hunting for sport, especially for the bobwhites, in agricultural areas of northern South America, and, in connection with this, some hunting regulations do exist in a few countries.

Several species of New World quails have been widely transplanted within the region and also to other parts of the world. The Northern Bobwhite and the California Quail have been extensively relocated, both from wild-trapped birds and from those raised in captivity, and it has now been suggested that the decline of the Northern Bobwhite in the north-eastern USA may have been accelerated by the release of large numbers of southern and pen-raised quails.

Both the Northern Bobwhite and the California Quail are naturalized well beyond their natural ranges. The California Quail is well established in New Zealand and Argentina, while the Northern Bobwhite is well established in several parts of the western USA, and in limited numbers in New Zealand. From South America, the Crested Bobwhite has been introduced and is now established on several Caribbean islands. Most of the other North American species have been introduced at one time or another in other parts of the USA, Europe, New Zealand and Australia, though generally without success.

Several of the New World quails are represented in some zoos or private collections, although they are generally not as popular as some of their galliform relatives. For example, specimens of many of the wood-quails can be found in one or more South American zoos, but most of these collections are small, containing only one to a few birds. Apart from a few North American species, members of Odontophoridae are rarely bred in captivity. The exception might be some of the

Although several other New World quail species seem to be able to get by with succulent plants, the California Quail selects its dry season habitat in accordance with its need for springs, streams, irrigation ditches or other permanent sources of drinking water. While incubation is carried out only by the female, the male, here partly hidden by the female, also participates in the care and guarding of the chicks.

[*Callipepla californica*.

Ardea]

collections of bobwhites found in Latin America, where there are reports of commercial breeding for eggs and for release.

Status and Conservation

The current status of the New World quails ranges from a species that may be critically endangered to others which are common and widespread. In order to detect any serious declines before it is too late to act, efforts are being made to determine the current situation and conservation requirements of all species, and this has been the main aim of the Conservation Assessment project (see page 472).

All of the better known species, those found predominantly in the USA, are widespread and common. Several of these species are widely hunted on a sustainable basis, and some are intensively managed for hunting, notably Northern Bobwhites, of which over 20 million are killed in the USA each year. But there is now concern regarding the trends in some populations of these species. Although populations of the Northern Bobwhite in the southern plains of the USA are stable to increasing, populations in traditional areas of the south-eastern and north-eastern USA have been undergoing a rather dramatic long-term decline. Much of this decline has been attributed, at least in part, to changes in land use. In the south-east, forestry practices directed towards the short-term rotational clear-cutting of pines are detrimental to populations. More traditional selective cutting and understorey burning, creating open pine woodlands with a grass understorey, result in much higher populations of quails. In the western USA, populations of California Quails and Scaled Quails have dwindled since 1960. The Mountain Quail has declined dramatically in the north-eastern portion of its range, but overall populations are stable.

Although Mexico contains the greatest diversity of quail species, including all of the species also found in the USA, very little is known about the conservation status of any of the species. Of the 11 polytypic species with ranges including Mexico, 60 of the 85 subspecies described are present in Mexico. Even for the well studied Northern Bobwhite, little is known about Mexican populations, although 16 of the 22 subspecies

are found there. An isolated subspecies, the Masked Bobwhite (*C. v. ridgwayi*) has only recently been studied in Mexico.

Among the species more adapted to xeric conditions, overgrazing can create problems by reducing both the vertical structure of the vegetation and the food supplies, although many of these species actually undergo population increases when their habitat is under light or moderate grazing by livestock. Livestock can even have impact on forest species, such as the Montezuma and Ocellated Quails, where grazing in the forest reduces the availability of important food plants.

Very little information is available for most of the forest-dwelling species of Central and South America. The Bearded Tree-quail (*Dendrortyx barbatus*) is considered the most critically threatened species in this group. Its former distribution was in the cloud forests of eastern Mexico, but these have now mostly been cleared. Surveys in the late 1980's revealed some populations, but these were not found again during subsequent searches in the 1990's; more intensive surveys for this species are planned for 1994. The other species currently considered to be seriously threatened is the Gorgeted Wood-quail (*Odonotophorus strophium*). This species was found in montane oak forests in the eastern Andes of central Colombia. A survey in the 1980's located populations in the vicinity of Virolin, Santander Department, and efforts have subsequently been made to establish a reserve there.

Several species of wood-quails are reckoned to be near-threatened mainly on the basis of their limited distributions, in conjunction with alterations of their habitat that are known to be occurring. Unfortunately, not enough is really known about many species to enable very accurate conservation assessments to be made. Nevertheless, the conversion of forest to agriculture in many parts of Central and South America must be considered a threat to many of these species, although it is not yet known how tolerant most species are to the fragmentation of the forest, or how well they can adapt themselves to use second-growth forest. The inconclusive evidence of scattered observations suggests that several species will utilize shaded fields of coffee, but not those plantations that lack the shade trees. However, at the same time there may also be some reason for concern about the possible impact that the pesticides used in the cultivation of coffee could have on these species.

The Long-tailed Tree-quail and the other two species of the genus *Dendrortyx* are, as their name suggests, the most arboreal members of the family. They roost in trees, sometimes at great heights, although they feed mainly on the ground. They are the largest of the New World quails, with the longest tails. Six subspecies have been described for the Long-tailed Tree-quail, all of them endemic to Mexico.

[*Dendrortyx macroura*, Mexico.]

Photo: Patricio Robles Gil]

Fortunately for a number of species with restricted ranges, such as the Venezuelan and Chestnut Wood-quails, there are national parks and reserves to protect some remaining habitat, but these isolated patches of suitable habitat are ever vulnerable to catastrophes, so that the status of these quails hangs in the balance. In addition, the distribution of parks and reserves is uneven in many zones: for example, in the western Andes several national parks help protect some of the remaining tracts of cloud forest, but there is little protection for forests at lower altitudes, and virtually no protection in the lower river valleys.

Although deforestation and agriculture may be considered the major threats to the forest quails, several other threats that are present might be important in some areas, for instance urbanization and hunting, which could both affect populations of quails. To date, outside the USA, no studies have been

carried out concerning the impacts of hunting on quail numbers. There is widespread but rather sporadic hunting of quails by indigenous peoples throughout much of Central and South America. Fortunately for the quails, the combination of their small size and the presence of many alternative prey species means that quails are often not considered worth the cost of a shotgun shell. The effects that hunting pressure might have on quail populations in the future, as alternative prey species decline due to deforestation, remain to be seen, but it is clear that the threat may well increase.

In addition to the rather intensively managed species in the USA, there are several other species that are apparently experiencing increases in terms of both population and distribution, due to the activities of humans. For instance, as a result of deforestation, the Crested Bobwhite has recently expanded its range into Costa Rica, where it may now be coming into contact with the Spot-bellied Bobwhite (*Colinus leucopogon*). The Crested Bobwhite is very common in the llanos of Venezuela and in parts of the major river valleys of Colombia, while the Spot-bellied Bobwhite is likewise common in Costa Rica. Nevertheless, there is some concern even for these species, which parallels the concerns for Galliformes inhabiting agricultural ecosystems in other parts of the world. The impacts of agricultural intensification and of the abundant use of pesticides are still unknown in this region, but they could prove to be very important.

Despite the existence of such threats, the first step that must be taken towards assuring the future of many of the Neotropical species involves a thorough study of the ecology, and in particular the habitat use, of such species. The paucity of data currently available on distribution, populations and precise habitat requirements limits the possibilities of making accurate conservation assessments and recommendations.

General Bibliography

- Alderton (1992), Brodkorb (1964), Carroll, Church & Kelsev (1994), Carroll, Kuvlesky *et al.* (1994), Delacour & Ridley (1985), Gutiérrez (1993), Gutiérrez *et al.* (1983), Johnsgard (1988), Kuroda (1970), McGowan, Carroll & Ellis-Joseph (1994), Peters (1934), Prager & Wilson (1976), Raethel (1988), Robbins (1981), Rutgers & Norris (1970), Sibley & Ahlquist (1990), Sibley & Monroe (1990), Sibley *et al.* (1988), Stock & Bunch (1982), Vaughan (1990), Verhegen (1956).

The Bearded Tree-quail is the most seriously threatened member of the family. It is thought to be in a critical situation, and its total population may not reach 1000 birds. Destruction of its forest habitat within its restricted range appears to be the main cause of its decline, although hunting and trapping have also played their parts. This bird was acquired with various other birds in a local market in Hidalgo, Mexico, in 1992.

[*Dendrortyx barbatus*, Mexico.]

Photo: Josep del Hoyo/ Lynx]

Genus *DENDRORTYX* Gould, 1844

1. Bearded Tree-quail

Dendrortyx barbatus

French: Colin barbu **German:** Bartwachtel **Spanish:** Colín Barbudo
Other common names: Bearded Tree-partridge/Wood-partridge

Taxonomy. *Dendrortyx barbatus* Gould, 1846, Jalapa, Veracruz, Mexico. Monotypic.

Distribution. EC Mexico. Formerly in Sierra Madre Oriental, from S San Luis Potosí to C Veracruz and Puebla; recently known only from Hidalgo.

Descriptive notes. 22-32 cm; estimated weight of male 459 g, of female 405 g. Tail longer in *Dendrortyx* than in other members of family; much shorter in present species than in congeners. Overall coloration reddish brown, with breast rufous cinnamon; cheeks, throat and upper breast bluish grey. Crown and short crest buffy brown; eyering, bill and legs red. Female smaller, with shorter tail. Immature has dark brown barring on flanks, and duller breast.

Habitat. Cloud forests and adjacent pine and oak forests at 1200-2200 m; local reports claim species was formerly present in Hidalgo in primary forest remnants at elevations of less than

915 m. Other reports indicate that birds can visit planted fields in forest clearings, when black beans ripening; known to use second growth forest, forest edge, gardens and bean plantations. Roosts above ground in trees.

Food and Feeding. One stomach contained fruit and seeds. Captive birds ate black beans and corn; also soft fruits, such as grapes and bananas. May eat ripe black beans in wild.

Breeding. Nesting season may be Apr-Jun; female with downy chicks recorded in Jun. Brood of 5 chicks said to have been captured in wild. In captivity, birds constructed nest in shallow depression with palm leaves. Eggs dull white, averaging 46.6 x 31.0 mm; incubation 28-30 days in captivity.

Movements. Presumably sedentary.

Status and Conservation. ENDANGERED. Mace-Landé: Critical. Restricted range; very little information available, but situation reckoned to be serious, as locally extinct in parts of range and severely threatened elsewhere. Total population might number less than 1000 birds; apparently still decreasing; locally common in small areas. Not recorded from San Luis Potosí since 1951, nor from Veracruz since 1968. Several patches of suitable habitat remain, where populations might occur, but most of cloud forest in former range now completely deforested. Main threats are rapid deforestation and hunting; illegally hunted and poisoned in places because of depredation on beans; sometimes trapped for sale in local markets. Three national parks in Veracruz include areas where species known to have occurred, but not recorded in recent years. Urgently requires research, surveys and conservation action in order to halt potential extinction.

Bibliography. Alderton (1992), Blake (1953), Collar & Andrew (1988), Collar *et al.* (1992), Davis (1952, 1972), Edwards (1989), Howell & Webb (1992b), Johnson (1973, 1988), Leopold (1959), Lowery & Newman (1951), Martin (1955), Ridgway & Friedmann (1946), Robbins (1981).

2. Long-tailed Tree-quail

Dendrortyx macroura

French: Colin à longue queue **German:** Langschwanzwachtel **Spanish:** Colín Rabudo
Other common names: Long-tailed Tree-partridge/Wood-partridge

Taxonomy. *Ortyx macroura* Jardine and Selby, 1828, Mexico = Valley of Mexico. Six subspecies recognized.

Subspecies and Distribution.

- D. m. macroura* (Jardine & Selby, 1828) - México (state) and Veracruz, EC Mexico.
- D. m. diversus* Friedmann, 1943 - NW Jalisco, WC Mexico.
- D. m. griseipennis* Nelson, 1897 - Pacific slope in México, Distrito Federal and Morelos, C Mexico.
- D. m. striatus* Nelson, 1897 - S Jalisco, Michoacán and Guerrero, WC Mexico.
- D. m. inexpectatus* Phillips, 1966 - Chilbancingo and Guerrero, S Mexico.
- D. m. oaxacae* Nelson, 1897 - W Oaxaca, S Mexico.

Descriptive notes. 29-37 cm; 350-465 g (unsexed), with male c. 450 g, female 374-446 g. Very long tail. Forehead, sides of head, throat and foreneck black; two white streaks above and below eye. Overall coloration chestnut and grey; breast bluish grey; upper back chestnut with wide grey margins; pale markings on wings and tail. Crown and short crest black with buff streaks; eyering, bill and legs red. Female smaller, with shorter tail. Immature spotted with dark brown on underside; less chestnut on breast. Races separated on coloration, notably on rump and breast; *oaxacae* has breast too boldly marked chestnut.

Habitat. Montane oak and pine forest and cloud forest at 1500-3300 m. Most often in dense undergrowth. **Food and Feeding.** Feeds on flowers, flower buds, small fruits and seeds. One crop contained various legumes, especially *Desmodium*. Scratches in leaf litter and humus, but also feeds in trees.

Breeding. Nesting season from late Apr, possibly to Dec. Two nests associated with rocky outcrops, another found at base of shrub; one nest (amongst rocks) covered by leaves and twigs from fallen tree, but other two not covered. Three clutches of 4 eggs; one with 6 eggs, but possibly referring to 2 females. Eggs pale cream with light brown spots, averaging 49.2 x 33.5 mm.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Mace-Landé: Safe. Status generally unknown; total population might number in region of 20,000-200,000 birds; possibly decreasing. Probably suffers habitat loss and some hunting pressure, but apparently not at risk. Extensive surveys required.

Bibliography. Alderton (1992), Biggs (1954), Binford (1989), Blake (1953), Davis (1972), Edwards (1989), Johnson (1973, 1988), Leopold (1959), Phillips (1966), Pielka (1948), Ridgway & Friedmann (1946), Rowley (1966, 1984), Schladach (1963), Skutch (1947b), Warner (1959), Zimmerman & Hurry (1951).

3. Buffy-crowned Tree-quail

Dendrortyx leucophrys

French: Colin à sourcils blancs **German:** Guatemala wachtel **Spanish:** Colín Cariclaro
Other common names: Buffy-crowned Tree-partridge, Highland Wood-partridge, Buff-fronted Quail

Taxonomy. *Ortyx leucophrys* Gould, 1844, Cobán, Vera Paz, Guatemala.

Race *hypospodius* has been considered separate species. Birds of Honduras and Nicaragua formerly awarded separate race, *nicaraguae*, but now included in nominate *leucophrys*. Two subspecies recognized.

Subspecies and Distribution.

- D. l. leucophrys* (Gould, 1844) - S Mexico (Chiapas), Guatemala, Honduras, E El Salvador and W Nicaragua.
- D. l. hypospodius* Salvin, 1896 - N Costa Rica.

Descriptive notes. 32-35.5 cm; estimated weight of male 397 g, of female 340 g. Fore-crown, supercilium, chin and throat white; ear-coverts black. Overall coloration chestnut and grey; breast and belly blue-grey with chestnut streaks. Crown, short crest and hindneck chestnut. Bare red eyering more elongated than in other *Dendrortyx*; bill black, legs orange-red. Female smaller, with shorter tail. Immature has buffy tips to greater primary coverts. Race *hypospodius* larger, rather darker and greyer, especially on underparts.

Habitat. Montane oak and pine forest and cloud forest at 300-2900 m. Found in second

growth and occasionally in coffee plantations. Roosts above ground in trees.

Food and Feeding. Seeds, flower buds and small fruits, including drupes. Has been observed scratching in oak leaf litter on forest floor.

Breeding. Recorded in May in Guatemala, Feb-Mar in El Salvador; chicks half-grown during Apr-Jul, Jun-Sept in Costa Rica. Possibly 4-5 eggs. Eggs reddish buff with reddish brown spots, averaging 44 x 30 mm.

Movements. Apparently sedentary. Moves about in coveys of 4-6 birds, but up to 12 during non-breeding season.

Status and Conservation. Not globally threatened. Mace-Landé: Safe. Virtually nothing known; total population might number in region of 20,000-200,000 birds; possibly decreasing. Deforestation may be a threat in some parts of range; some trapping known to occur. Extensive surveys required.

Bibliography. Alderton (1992), Baepfer (1962), Blake (1953, 1977), Diekmann (1987b), Dickey & van Rossem (1938), Edwards (1989), Griscom (1932), Johnson (1973, 1988), Land (1970), Leopold (1959), Montre (1968), Ridgely & Gwynne (1989), Ridgway & Friedmann (1946), Saunders *et al.* (1950), Slud (1964), Stiles & Skutch (1989), Wagner (1953), Wetmore (1941).

Genus *OREORTYX* Baird, 1858

4. Mountain Quail

Oreortyx pictus

French: Colin des montagnes **German:** Bergwachtel **Spanish:** Colín Serrano

Taxonomy. *Ortyx picta* Douglas, 1829, New California = Linn Co., Oregon, USA.

Race *palmeri* considered synonymous with nominate. Five subspecies recognized.

Subspecies and Distribution.

- O. p. pictus* (Douglas, 1829) - SW Washington to C California, W USA; also (probably introduced) Vancouver I. SW Canada, and W Washington, NW USA.
- O. p. plumiferus* (Gould, 1938) - S Washington to W Nevada and NE & NC California, W USA.
- O. p. russelli* Miller, 1946 - S California, W USA.
- O. p. eremophila* van Rossem, 1937 - S & WC California and SW Nevada, W USA, to extreme N Baja California, NW Mexico.
- O. p. confinis* Anthony, 1889 - N Baja California, Mexico.

Introduced locally in W Idaho, NW USA, where may be native too.

Descriptive notes. 26-28 cm; 200-290 g, with sexes apparently similar. Largest quail of North America. Long black sword-shaped crest highly distinctive. White eyeline continuing onto throat; chin and throat cinnamon. Overall coloration dark blue-grey; belly chestnut with white streaks on flanks; flight-feathers with white margin. Bill black, legs brown. Female similar, with smaller crest. Immature has buff-tipped greater primary coverts. Races separated on coloration, mainly of back and breast.

Habitat. Variable, depending on population; mixed evergreen forest and chaparral; brushy oak and manzanita; forest edge; brushy thick-

ets; and farms. During summer occurs at 500-3000 m, generally lower during winter. Found at higher altitude and on steeper slopes than sympatric populations of *Callipepla californica*.

Food and Feeding. Mainly seeds and bulbs, but also fruits, flowers and green herbage. Most important plant items in California include *Lithophragma*, *Quercus*, *Stellaria*, *Erodium*, *Trifolium* and *Rhus*. Few arthropods taken even by young chicks. Foraging methods recorded include scratching in litter, digging, jumping, acorn shelling and tree climbing. Standing water required.

Breeding. Mar-Jul, occurring earlier in S, later in N; peak hatching May-Jun. Nests located under branches or shrubs, close to water. Clutch size 9-10; Eggs pale reddish buff, averaging 34.5 x 26.5 mm.

Incubation 21-25 days; carried out by female, but some evidence of male assistance. Brood may be raised by either adult of pair or by both; no evidence to date of any birds laying second clutch.

Movements. Less sedentary than other related species; evidence of altitudinal migrations of over 50 km in some populations. Coveys probably comprise family groups; normally 5-9 birds, but up to 20. **Status and Conservation.** Not globally threatened. Mace-Lande: Safe. Overall population levels stable, probably numbering over 1,000,000 birds. Important gamebird in W USA: widespread local declines and extinctions in NE portion of range, e.g. only three small populations left in Idaho. In areas with population declines, major threats include construction of dams and impoundments, agricultural conversion and grazing. In Mexico, threatened by overgrazing.

Bibliography. Alderton (1992), Blake (1953), Block *et al.* (1984, 1991), Brennan (1985, 1990, 1991a), Brennan & Block (1985, 1986), Brennan *et al.* (1985, 1986, 1987), Browning (1977), Church & Dailey (1993), Edwards (1989), Grinnell *et al.* (1918), Gutiérrez (1975, 1980), Gutiérrez *et al.* (1983), Johnsgard (1973, 1975), Leopold (1959), Lever (1987), McLean (1930), Ormiston (1966), Pine (1981), Ridgway & Friedmann (1946), van Rossem (1937), Terres (1980), Yocom & Harris (1953).

Genus *CALLIPEPLA* Wagler, 1832

5. Scaled Quail

Callipepla squamata

French: Colin écaillé German: Schuppenwachtel Spanish: Colín Escamado
Other common names: Blue Quail

Taxonomy. *Ortyx squamatus* Vigors, 1830, interior of Mexico.

Sometimes considered conspecific with *C. douglasii*. Four subspecies recognized.

Subspecies and Distribution.

C. s. hargrivi Rea, 1973 - SE Colorado, SW Kansas, N New Mexico, W Oklahoma and NW Texas, WC USA.

C. s. pallida Brewster, 1881 - S Arizona, S New Mexico and W Texas, SC USA, to N Chihuahua and N Sonora, NW Mexico.

C. s. squamata (Vigors, 1830) - N Sonora and N Tamaulipas S to Valley of Mexico, Mexico.

C. s. castanogastris Brewster, 1883 - S Texas, S USA, and NE Mexico.

Introduced to C Washington and Nevada, W USA.

Descriptive notes. 22-29 cm; 151-202 g, with sexes apparently similar. Distinctive short, bushy crest is mainly buff to white, with white tip (cottontop). Overall coloration blue-grey. Back, breast and belly blue-grey, fading to buff below, with black feather tips, producing scaly appearance; buff or white streaks on folded wing and flanks. Bill black, legs greyish black. Female has smaller crest; brown streaks on face and throat. Immature has greater primary coverts tipped with buff. Races separated in tone of grey on upperparts, darker in *castanogastris*, paler in *pallida*; also in colour of belly, chestnut in *castanogastris*.

Habitat. Desert scrub and grasslands; prefers some variation, and avoids uninterrupted stretches of grassland. Often occurs where standing water available.

Food and Feeding. Takes wide variety of food types, especially seeds, insects and green herbage. In Texas, commonest items were seeds of honey mesquite, sunflowers, common Russian thistle and sorghum, herbage of lanceleaf krameria and milkvetch, and insects such as grasshoppers and beetles. In Mexico, takes seeds of *Bidens*, corn cockle, *Croton*, foxtail, *Panicum* and Johnson grass. Fruits of *Atriplex* and *Mahonia* also eaten.

Breeding. Jun-Oct (rainy season). Nests located under shrubby vegetation e.g. soapweed or sand sage, and other grasses or forbs. Clutch size averages 12-7-14 in USA; average 12 eggs (9-16) in Mexico. Eggs dull white with brown or white speckling, averaging 32.5 x 25.0 mm. Incubation 21-23 days, by female; assistance by male extremely rare. Double-clutching reported. Average brood size in USA 7-8-11-5.

Movements. Sedentary; birds generally move about less than 2 km, although some movements of over 100 km reported. Moves about in coveys, normally of 10-40 birds, but sometimes up to 200. Home range of 10-34 ha.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Total population probably numbers over 1,000,000 birds. Important gamebird in SW USA; has declined rather dramatically in USA since 1960. Mesquite control detrimental to populations. Has benefited from clearing of pine and oak forest, and also from overgrazing in past.

Bibliography. Anderson (1978), Ault & Storer (1983), Blake (1953), Brown, D.E. (1989), Cain *et al.* (1987), Campbell, D.K. *et al.* (1973), Campbell, H. (1968), Campbell, H. & Harris (1965), Campbell-Kissok *et al.* (1985), Church & Dailey (1993), Davis *et al.* (1975), Dixon (1959), Edwards (1989), Pigge (1946), Fleming & Baker (1963), Hammenquist-Wilson *et al.* (1987), Hoffman (1965), Johnsgard (1973, 1975), Kelso (1937), Lehmann (1984), Lehmann & Ward (1941), Leopold (1959), Ligon (1961), McCabe (1954), Medina (1988), Rea (1973), Ridgway & Friedmann (1946), van Rossem (1945), Russell (1932), Saunders & Parrish (1987), Schemnitz (1959, 1961, 1964), Smith & Cain (1984), Storer (1984), Terres (1980), Urban (1959), Wallino (1956a, 1956b, 1957).

6. Elegant Quail

Callipepla douglasii

French: Colin élégant German: Douglaswachtel Spanish: Colín Elegante
Other common names: Douglas Quail

Taxonomy. *Ortyx douglasii* Vigors, 1829, Mazatlan, Sonora, Mexico.

Often placed in *Lophortyx*. Sometimes considered conspecific with *C. squamata*. Some debate over status and relationship of races *douglasii* and *impedita*; validity of *languens* also questionable. Five subspecies normally recognized.

Subspecies and Distribution.

C. d. bensoni Ridgway, 1887 - Sonora, NW Mexico.

C. d. languens (Friedmann, 1943) - N Chihuahua, NW Mexico.

C. d. douglasii (Vigors, 1829) - S Sonora, Sinaloa, NW Durango and N Nayarit, W Mexico.

C. d. impedita (Friedmann, 1943) - C & S Nayarit, W Mexico.

C. d. teres (Friedmann, 1943) - NW Jalisco, WC Mexico.

Descriptive notes. 21-24 cm, 160-190 g. Males slightly larger. Long vertical crest is orange buff in male. Overall coloration blue-grey. Crown, sides of head and neck and throat grey with black streaks. Lower breast and belly grey with rows of white spots with black margins. Bill and legs black. Female

Family ODONTOPHORIDAE (NEW WORLD QUAILS) SPECIES ACCOUNTS

averaging 33.9 x 23.9 mm. Incubation 22-23 days.

Movements. Presumably sedentary. Coveys of 6-20 birds observed.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Status not well known; total population might number c. 50,000-100,000 birds. Reported to be common in several areas in 1960's. Human activity has apparently been responsible for population increases in some areas.

Bibliography. Alden (1969), Alderton (1992), Blake (1953), Davis (1972), Edwards (1989), Escalante (1988), Johnsgard (1973, 1988), Leopold (1959), Miller (1905), Raethel (1988), Ridgway & Friedmann (1946), Robbins (1981), van Rossem (1945).

7. California Quail

Callipepla californica

French: Colin de Californie German: Schopf wachtel Spanish: Colín de California
Other common names: Valley Quail

Taxonomy. *Tetrao californicus* Shaw, 1798, Monterey, California, USA.

Often placed in *Lophortyx*. Sometimes considered conspecific with *C. gambelii*, with which forms superspecies. Eight subspecies recognized.

Subspecies and Distribution.

C. c. californica (Shaw, 1798) - N Oregon and W Nevada, NW USA, S to Los Coronados Is, Baja California, NW Mexico; also (probably introduced) from S British Columbia, SW Canada, SE to Colorado, WC USA.

C. c. orecta (Oberholser, 1932) - SE Oregon and extreme NE California, W USA.

C. c. brunnescens (Ridgway, 1884) - coastal N California to SC California, W USA; also (probably introduced) Vancouver I, Canada.

C. c. catalinensis (Grinnell, 1906) - Santa Catalina I, off SW California, W USA; also (probably introduced) nearby Santa Rosa and Santa Cruz Is.

C. c. canfieldae (van Rossem, 1939) - EC California, W USA.

C. c. plumbea (Grinnell, 1926) - S California, W USA, to N Baja California, NW Mexico.

C. c. decolorata (van Rossem, 1946) - C & S Baja California, NW Mexico.

C. c. achruster (Peters, 1923) - extreme S Baja California, W Mexico.

Introduced to Chile, Argentina, New Zealand, King I (Australia) and Hawaii.

Descriptive notes. 23-27 cm; male 176 g, female 162 g. Long black teardrop-shaped crest. Distinctive black and white pattern on face and throat separates from all except *C. gambelii*; differs from that species in having belly buff with black and brown feather tips, giving scaly pattern. Overall coloration blue-grey; crown chestnut; white streaking on flanks. Bill black, legs grey. Female has smaller crest; head and throat greyish with dark streaks. Immature has buff-tipped greater primary coverts. Races separated on general coloration, especially different tones of greyish or brownish back; also to some extent on size.

Habitat. Very diverse habitats, depending on area, and including brushland, chaparral, desert, evergreen forest, forest edge, grassland and agricultural land.

Food and Feeding. Mainly seeds and bulbs of *Lupinus*, *Lotus*, *Erodium*, *Trifolium*, *Medicago*, *Phoradendron*, *Salsola kali*, *Quercus*, *Hypochoeris* and barley; also takes green herbage. Scratches in litter for seeds; also plucks leaves from growing vegetation. Standing water needed.

Breeding. Early Apr (in S) or May-Jun (in N) to Jul-Aug. Nest is depression in ground lined with grass. Clutch size 13-17 (up to 28). Eggs creamy white with light brown blotches, averaging 31.6 x 24.1 mm. Incubation 22-23 days by female; male assists with brood rearing. Double-clutching reported. Low nest success, often of under 20%.

Movements. Sedentary; maximum movements recorded less than 27 km. Typically circulates in coveys of 25-40 birds, but up to 1000 seen together. Home range of 2-18 ha; smaller in summer, larger in winter.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Important gamebird in W USA, with over 2,000,000 harvested per year; however, has declined rather dramatically in USA since 1960. Grazing can have detrimental effects, but undergrazing in mesic areas also shown to have a negative impact on populations.

Bibliography. Anthony (1970), Barclay & Bergerud (1975), Bartholomew & Dawson (1958), Bartholomew & MacMillan (1961), Blake (1953), Blakely *et al.* (1990), Blus *et al.* (1985), Brown & Gutiérrez (1980), Chandler (1970), Church & Dailey (1993), Crawford (1978b), Crispens *et al.* (1960), Duncan (1968), Edwards (1989), Emilen (1939, 1940), Fjeldså & Krabbe (1990), Francis (1965, 1967, 1970), Genelly (1955), Glading (1938a, 1938b, 1941), Glading *et al.* (1945), Gullion & Christensen (1967), Gutiérrez (1980), Gutiérrez *et al.* (1983), Hill & Wiggins (1948), Howard & Emilen (1942), Johnsgard (1973), Johnson (1965), Jones (1969), Kilbride *et al.* (1992), Leopold (1959, 1977), Lever (1987), Lewin (1963, 1965), Linsdale (1936), McMillan (1964), Oates & Crawford (1983), Raitt (1960, 1961), Raitt & Genelly (1964), Shields & Duncan (1966), Stinnett & Klebenow (1986), Sumner (1935), Terres (1980), Williams, G.R. (1952), Williams, H.W. (1969), Zink *et al.* (1987).

8. Gambel's Quail

Callipepla gambelii

French: Colin de Gambel German: Helm wachtel Spanish: Colín de Gambel
Other common names: Desert Quail

Taxonomy. *Lophortyx gambelii* Gambel, 1843, west of California = south Nevada, USA.

Often placed in *Lophortyx*. Sometimes considered conspecific with *C. californica*, with which forms superspecies. Seven subspecies recognized.

Subspecies and Distribution.

C. g. gambeli (Gambel, 1843) - S Utah and Nevada, W USA, S to Baja California, NW Mexico.
C. g. sana (Mearns, 1914) - W Colorado, WC USA.
C. g. ignoscens (Friedmann, 1943) - S New Mexico and extreme W Texas, SC USA.
C. g. pembertonii (van Rossem, 1932) - Tiburon I, in Gulf of California, NW Mexico.
C. g. fulvipes Nelson, 1899 - NC to SW Sonora, NW Mexico; possibly also SE Arizona and SW New Mexico, SW USA.
C. g. stephensi (Phillips, 1959) - S Sonora, NW Mexico.
C. g. friedmanni (Moore, 1947) - coastal and NW Sinaloa, NW Mexico.
Introduced (*gambeli*) to Idaho, NW USA.

Descriptive notes. 23-27 cm; male 161 g, female 156 g. Long black teardrop-shaped crest. Distinctive black and white pattern on face and throat separates from all except *C. californica*; differs from that species in having belly buff with black median patch. Overall coloration blue-grey; crown reddish brown; brown and white streaking on flanks. Bill black, legs grey. Female has smaller crest; head and throat greyish with dark streaks. Immature has buff-tipped greater primary coverts. Races separated on tone of grey on upperparts, and of buff on belly.

Habitat. Occurs in three types of desert: low warm desert valleys dominated by mesquite

(*Prosopis*); upland warm deserts dominated by cat's claw (*Acacia*), yucca (*Yucca*), and prickly-pear cactus (*Opuntia*); and cool desert dominated by sagebrush (*Artemisia*). Also frequents irrigated agricultural habitats.

Food and Feeding. Takes wide variety of food types: mainly flowers and seeds; generally few insects, although more eaten by chicks. Plants most commonly recorded are deerweed (*Lotus*), filaree (*Erodium*), mesquite, and alfalfa (*Medicago*). Water apparently needed when succulent plants are not available.

Breeding. Late Apr-Aug. Nest is shallow depression concealed in grass or bush. Clutch size 12-14 (up to 19). Eggs white with purplish brown splotches, averaging 32.0 x 24.0 mm. Incubation 23 days, by female; male assists in rearing of brood. Double-brooding reported.

Movements. Sedentary; maximum movement recorded was under 16 km. Coveys average 12.5 birds, but up to 40. Home range c. 7-40 ha.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Total population numbers over 1,000,000 birds. Populations in USA stable since 1960's. Important gamebird in SW USA. Tolerant of conversion of desert to cropland, although heavy grazing can reduce populations. Status in Mexico poorly known, but probably secure.

Bibliography. Alden (1969), Beck *et al.* (1973), Blake (1953), Brown, D.E. (1989), Campbell (1957), Church & Dailey (1993), Edwards (1989), Ellis & Stokes (1966), Goldstein (1983, 1984), Gorsuch (1934), Gullion (1960, 1962), Hungerford (1962, 1964), Johnson (1973, 1975), Leopold (1959), Lever (1987), Ligon (1961), Phillips (1958), Pielka (1948), Raitt & Ohmart (1966, 1968), Ridgway & Friedmann (1946), van Rossem (1945), Sutton & Phillips (1942), Swank & Gallizioli (1954), Terres (1980), Vorhies (1928).

Genus *PHILORTYX* Gould, 1846

9. Barred Quail

Philortyx fasciatus

French: Colin barré

German: Bindenwachtel

Spanish: Colín Bandeado

Other common names: Banded Quail

Taxonomy. *Ortyx fasciatus* Gould, 1844, California; error, Mexico. Monotypic.

Distribution. SW Jalisco to SE Guerrero, Morelos and Puebla, WC Mexico.

Descriptive notes. 18-21 cm; 115-160 g, with male averaging 130 g, female 126 g. Breast and belly white with black barring; overall coloration greyish brown to grey; head greyish brown, with white chin and throat. Straight black and brown crest, with rufous-tipped feathers. Bill black, legs brown. Female has shorter crest. Immature has black feathering on face, chin and throat.

Habitat. Arid and semi-arid tropical scrub, weed-bordered agricultural land, and overgrown pastures, from sea-level to over 1500 m. More common at lower elevations.

Food and Feeding. Mainly seeds of *Desmodium*

and *Crotalaria*; also seeds of sunflower, thistles, corn cockle, *Croton* and cultivated beans and sesame. In addition, takes some insects, e.g. leaf beetles and larvae of Lepidoptera. Drinks water during dry season.

Breeding. Nesting in Aug and Sept. In captive birds; nest made of grass with partial roof; average clutch size 5.5 (3-7); eggs laid at intervals of 2 days; incubation 22-6 days (21-23). Eggs white, averaging 30.2 x 23.7 mm.

Movements. Sedentary. Often occurs in coveys of 5-20 birds; overall average covey size of 12 birds, but only 5.8 in Jun; in W Mexico, coveys of 10-40 in Guerrero, and 10-20 in Jalisco.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Total population may number under 100,000 birds, but thought to be stable. Limited range; very little information available. Potential threats include overgrazing and agricultural intensification. Hunting occurs in some areas.

Bibliography. Alderton (1992), Binford (1989), Blake (1953, 1977), Blake & Hanson (1942), Davis, L.I. (1972), Davis, W.B. (1944), Edwards (1989), Johnson (1973, 1988), Leopold (1959), Ridgway & Friedmann (1946), Schaldach (1963), Zimmerman & Harry (1951).

Genus *COLINUS* Goldfuss, 1820

10. Northern Bobwhite

Colinus virginianus

French: Colin de Virginie

German: Virginiawachtel

Spanish: Colín de Virginia

Other common names: Common Bobwhite, Bobwhite; Rufous-bellied Bobwhite (*pectoralis*); Masked Bobwhite (*ridgwayi*); Black-headed Bobwhite (*atriceps*)

Taxonomy. *Tetrao virginianus* Linnaeus, 1758, America = South Carolina, USA.

Sometimes considered conspecific with *C. nigrogularis*. Several races have at times been considered full species. Validity of race *nelsoni* questionable. Twenty-two subspecies recognized.

Subspecies and Distribution.

C. v. marilandicus (Linnaeus, 1758) - SE Maine to C Virginia, NE USA.
C. v. virginianus (Linnaeus, 1758) - Virginia to N Florida and W to Alabama, E USA.
C. v. floridanus (Coe, 1872) - peninsular Florida, E USA.
C. v. cubanensis (G. R. Gray, 1846) - Cuba and I of Pines.
C. v. mexicanus (Linnaeus, 1766) - E USA; W of *marilandicus* and E of *taylori*.
C. v. taylori Lincoln, 1915 - South Dakota to N Texas to W Missouri, C USA.
C. v. texanus (Lawrence, 1853) - SW Texas, USA, and Coahuila, Nuevo Leon and Tamaulipas, NE Mexico.
C. v. ridgwayi Brewster, 1885 - NC Sonora, Mexico; reintroduced to SE Arizona, SW USA, where extirpated in past.
C. v. maculatus Nelson, 1899 - C Tamaulipas to N Veracruz and SE San Luis Potosí, NE Mexico.
C. v. aridus Aldrich, 1942 - C Tamaulipas to SE San Luis Potosí, NE Mexico.
C. v. graysoni (Lawrence, 1867) - SE Nayarit and S Jalisco to Morelos, S Hidalgo and SC San Luis Potosí, C Mexico.
C. v. nigripictus Nelson, 1897 - Puebla, Morelos and México (state), Mexico.
C. v. pectoralis (Gould, 1843) - E slope of mountains of C Veracruz, E Mexico.
C. v. godmani Nelson, 1897 - lowland Veracruz, E Mexico.
C. v. minor Nelson, 1901 - NE Chiapas and adjacent Tabasco, S Mexico.
C. v. atriceps (Ogilvie-Grant, 1893) - extreme W Oaxaca, S Mexico.
C. v. thayeri Bangs & Peters, 1928 - NE Oaxaca, S Mexico.
C. v. harrisoni Orr & Webster, 1968 - SW Oaxaca, S Mexico.
C. v. coyoclos (P. L. S. Müller, 1776) - coast of E Oaxaca and N Chiapas, S Mexico.
C. v. nelsoni Brodtkorb, 1942 - S Chiapas, Mexico.
C. v. salvini Nelson, 1897 - coast of S Chiapas, Mexico.
C. v. insignis Nelson, 1897 - S Chiapas, S Mexico, and Huehuetenango, W Guatemala.
Introduced to British Columbia (Canada), Puerto Rico, Hawaii, New Zealand and West Indies; also (*taylori*) to Washington, Oregon and Idaho, NW USA; may be introduced to I of Pines and Cuba, although this population usually awarded subspecific status.

Descriptive notes. 20-25 cm. Size increases from S to N; average 129 g (Chiapas); 159 g (San Luis Potosí); male 173 g, female 170 g (E USA). Lacks prominent crest. Extremely variable, both within and among races, with greatest variation on head and underparts; overall coloration involves combinations of grey, brown and white. Several races have white supercilium and black or brown eyeline, combined with white moustachial streak or all white throat; others have chin and throat blackish, with breast often blackish or brownish. Bill black, legs horn-coloured. Female lacks striking black and white facial patterns; head and

throat mostly buff. Immature has greater primary coverts tipped buff. Races separated mainly on plumage, but also on size: pattern of white eyestripe bordered by black and white throat found in those of USA and some of Mexico.

Habitat. Varies with population; includes pine woodlands, woodland edge, shrubs, agricultural fields, pastures, rangeland and fallow fields.

Food and Feeding. In Mexico, primarily seeds of sunflowers, foxtails, panic grass, thistles, and *Desmodium*; oak acorns, and cultivated frijoles, corn, wheat and tomatoes. In Alabama, S USA, most important food is legume seeds. In several areas dominated by grassland, diet includes *Croton*, *Sesbania*, *Panicum*, *Ambrosia* and *Helianthus*. In agricultural areas, diet varies according to major crops, including corn, sorghum, oats, soybeans and wheat; also oak acorns. Insects important during summer.

Breeding. Variable in USA, with peak in Apr-Jun, earlier in S, later in N; Apr-Jun in Mexico, where possibly later in Oaxaca, to coincide with rainy season. Nest constructed in depression on ground and lined with dead vegetation; standing vegetation usually covers nest from above. Clutch size averages 12.5-14.4 eggs (10-15); clutch of 8 eggs in Oaxaca, S Mexico; generally fewer eggs in second clutches. Incubation 23 days. Nest success 20-40%. Eggs dull white, but can be stained; average 30 x 24 mm.

Movements. Sedentary, except during autumn dispersal. Normally forms coveys; on average of 12 birds (8-20) in Mexico; average 13.8 or 14.3 in USA, but up to 28 birds. Home range of as much as 25 ha, but usually under 10 ha.

Status and Conservation. Not globally threatened. Mace-Land: Safe. In USA, over 20,000,000 individuals per year killed by hunters. Populations in parts of the USA intensively studied and managed; however, populations in many areas declining, and contraction of range in NE USA; severe declines in traditional areas of SE USA. Mexican populations not well known and some subspecies could be threatened. Race *ridgwayi* considered endangered in USA, and subject to intensive restoration effort in Arizona; small population in Sonora, NW Mexico, could be threatened. Major threat in Mexico is overgrazing. Other potential threats include pesticides, in agricultural areas, and hunting. Subspecies *ridgwayi* on CITES I.

Bibliography. Aldrich (1946), Alvarez del Toro (1952), Bauer (1985), Binford (1989), Blake (1953, 1977), Brennan (1991b), Briggs (1954), Brodtkorb (1943), Brown & Ellis (1977), Brown & Gutiérrez (1980), Burger (1993), Burger *et al.* (1990), Cain *et al.* (1982), Carriannell Kissack *et al.* (1984, 1985), Church & Dailey (1993), Church & Taylor (1992), Coggins (1986), Davis (1972), DeMaso *et al.* (1992), Dimmick (1975), Droege & Sauer (1990), Ellis, D.H. & Serafin (1977), Ellis, D.H. *et al.* (1978), Ellis, J.A. *et al.* (1969), Ellsworth & Roseberry (1988), Ellsworth *et al.* (1989), Escalante (1988), Gilpin (1982), Gilpin & Hungerford (1977), Gissom (1932), Guthery (1986), Guthery & Koerth (1992), Guthery *et al.* (1988), Gutiérrez *et al.* (1983), Hammerquist-Wilson & Crawford (1987), Johnson & Guthery (1988), Kahal & Thompson (1963), Kiel (1976), Klimstra & Roseberry (1975), Koerth & Guthery (1991), Landers & Johnson (1976), Landers & Mueller (1989), Lehmann (1953, 1984), Lever (1987), Ligon (1952, 1961), Lowery & Dalquest (1951), Lyon (1962), Marsden & Baskett (1958), McInteer (1986), McRae & Dimmick (1982), Morrison & Lewis (1972), Murphy & Baskett (1952), Murray & Frye (1957), O'Brien *et al.* (1985), Pappe & Sweeney (1944), Pringle (1948), Pulliam, Moore *et al.* (1989), Pollock, Wuerstein *et al.* (1989), Rice *et al.* (1993), Robel & Arruda (1986), Robel & Fretwell (1970), Roseberry & Klimstra (1984, 1993), Roseberry (1969), van Rossem (1945), Rowley, 1984, Schmitt (1964), Schiesskey *et al.* (1982), Scott, T.G. 11. Black-throated Bobwhite

Colinus nigrogularis

French: Colin à gorge noire German: Schwarzkehlwachtel Spanish: Colín Gorginegro
Other common names: Yucatan Bobwhite

Taxonomy. *Ortyx nigrogularis* Gould, 1843, Mexico = Belize.

Possibly conspecific with *C. virginianus*. Four subspecies recognized.

Subspecies and Distribution.

C. n. persicus Van Tyne & Trautman, 1941 - Progreso area of Yucatán, SE Mexico.

C. n. caboti Van Tyne & Trautman, 1941 - N Campeche, Yucatán (except Progreso area) and N Quintana Roo, SE Mexico.

C. n. nigrogularis (Gould, 1843) - Belize and N Guatemala.

C. n. segoviensis Ridgway, 1888 - E Honduras and NE Nicaragua.

Descriptive notes. 18-21.5 cm; 126-144 g, with sexes apparently similar. Distinctive face pattern separates from congeners. Forehead, sides of head, and throat black; small crest and crown chestnut; white stripes above and below eye. Overall coloration is mixture of rufous, white and black. Back of neck and upper back cinnamon with rows of buff and white spots; back chestnut with grey feather margins, rump olive brown and grey, scapulars and upperwing-coverts cinnamon with grey, chestnut and black spots. Breast and belly white with rows of black "V"s; flanks white with brown and black feather margins.

Bill black and legs brown or slate blue. Female has crown buff with rows of small black spots; sides of head and neck buff fading to whitish on throat; back and rump mottled olive brown with cinnamon and black "V"s; breast and belly light grey with small black "V"s becoming larger on belly. Immature has buff-tipped greater primary coverts. Races separated on size, plumage tone and extent of white spotting.

Habitat. Brush, woodland edge, forest openings with weeds, pine savannas and agricultural land. Apparently best habitat in areas where henequin is planted. During dry seasons often associated with standing water.

Food and Feeding. Known to take seeds, including *Desmodium*.

Breeding. Laying Apr-Aug or later; most reports of adults in breeding condition or clutches during Jun-Aug; newly-hatched chicks in Nov. Nest in hollow on ground lined with grass. Eggs pale buff to white, sometimes with small dark spots; size averages 30.5 x 22.7 mm.

Movements. Sedentary. Coveys of 12-20 birds reported.

Status and Conservation. Not globally threatened. Mace-Landé: Safe. Status not well known; total population may number 100,000-1,000,000 birds, and thought to be stable. Reported to be common in many areas, and has benefited from clearing of forest for agricultural land. However, population surveys and research on biology of species still needed.

Bibliography. Alderton (1992), Blake (1953, 1977), Davis (1972), Edwards (1989), Howell (1971), Johnsgard (1973, 1988), Klaas (1968), Land (1970), Lee (1966), Leopold (1959), Monroe (1968), Nelson (1932), Paynter (1955), Ridgway & Friedmann (1946), Russell (1964), Saunders *et al.* (1950), Smith (1966), Stone (1890), Traylor (1941), Van Tyne (1935), Van Tyne & Trautman 1941).

12. Spot-bellied Bobwhite

Colinus leucopogon

French: Colin à face blanche German: Fleckenwachtel Spanish: Colín Gorgiblanco
Other common names: White-breasted Bobwhite (*hypoleucus*); Sclater's Bobwhite (*sclateri*); Dickey's Bobwhite (*dickeyi*)

Taxonomy. *Ortyx leucopogon* Lesson, 1842, San Carlos = la Unión, El Salvador.

Often considered conspecific with *C. cristatus*. Several races have at times been considered full species. Race *nicaraguae* no longer considered valid. Six subspecies recognized.

Subspecies and Distribution.

C. l. incanus Friedmann, 1944 - S Guatemala.

C. l. hypoleucus (Gould, 1860) - W El Salvador and adjacent Guatemala.

C. l. leucopogon (Lesson, 1842) - SE El Salvador and W Honduras.

C. l. leylandi (Moore, 1859) - NW Honduras.

C. l. sclateri (Bonaparte, 1856) - SW & C Honduras to NW Nicaragua.

C. l. dickeyi Conover, 1932 - NW & C Costa Rica.

Descriptive notes. 19-23 cm; estimated weight of male 144 g, of female 115 g. Small crest olive brown with buff feather margins. Overall coloration mottled grey and dusky, also white. Distinctive face patterns separate from congeners. Plumage very variable, with head and underparts of two types: northern (*leucopogon* and N), with forehead, supercilium and throat, and in some races breast and belly, white; and southern (*leylandi* and S), with forehead black or brown, supercilium white or buff, throat brown with black border or black with white or buff border, hindneck spotted with black, and breast and belly reddish brown. Back and rump mottled grey and brown with black vermiculations. Bill black and legs bluish horn. Female similar, but throat buff and spotted with black; breast and belly buff with black and tan streaks or bars. Immature similar to female. Races separated on plumage colours, especially of head and underparts.

Bill black and legs bluish horn. Female similar, but throat buff and spotted with black; breast and belly buff with black and tan streaks or bars. Immature similar to female. Races separated on plumage colours, especially of head and underparts.

Habitat. Arid lower tropical zone, including open pine forest, grassland, brush, woodland edges and agricultural land, at altitudes under 1800 m.

Food and Feeding. Small seeds, especially sacaton bunch grass and small buds in El Salvador. Seeds, fruits and insects in Costa Rica; sometimes feeds on beans and rice crops.

Breeding. Pairing in Apr, nesting generally May-Sept, although often later in El Salvador. Nests on ground in bowl of herbage under thick vegetation cover. Clutch size of 10 eggs in Costa Rica. Eggs white, averaging 31.1 x 25 mm.

Movements. Presumably sedentary. One covey of 8 birds observed; coveys of 3-15 birds in Costa Rica.

Status and Conservation. Not globally threatened. Mace-Landé: Safe. Status not well known; total population might number under 500,000 birds, but thought to be relatively stable. Reported common in many parts of range and range expansion reported. This species has benefited from activities of humans, especially through clear-cutting of forest and development of agriculture. Nevertheless, population surveys and research needed.

Bibliography. Alderton (1992), Blake (1977), Dickey & van Rossem (1938), Griscom (1932), Johnsgard (1988), Land (1970), Monroe (1968), Ridgway & Friedmann (1946), Saunders *et al.* (1950), Schonwetter (1967), Shud (1964), Stiles & Skutch (1989), Stone (1932), Wetmore (1965).

13. Crested Bobwhite

Colinus cristatus

French: Colin huppé German: Haubenwachtel Spanish: Colín Crestudo

Taxonomy. *Tetrao cristatus* Linnaeus, 1766, Mexico, Guiana = Curaçao.

Often considered conspecific with *C. leucopogon*. Race *leucotis* has been considered distinct species. Validity of several Venezuelan races possibly in question, due to overlapping distribution and lack of barriers. Nominat race sometimes subdivided, with recognition of race *continentis*. Type locality of species questionable. Thirteen subspecies recognized.

Subspecies and Distribution.

C. c. mariae Wetmore, 1962 - Chiriquí area, Panama.

C. c. panamensis Dickey & van Rossem, 1930 - Pacific slope of W Panama.

C. c. decoratus (Todd, 1917) - Caribbean coast of Colombia.

C. c. cristatus (Linnaeus, 1766) - NE Colombia and Barinas, NW Venezuela, in and near Guajira Peninsula; Curaçao and Aruba, where possibly introduced.

C. c. littoralis (Todd, 1917) - N base of Santa Marta Mts, NE Colombia.

C. c. badius Conover, 1938 - Cauca Valley to W slope of Western Andes, W Colombia.

C. c. leucotis (Gould, 1844) - upper and middle sections of Magdalena Valley, and middle Sinú Valley, C Colombia.

C. c. bogotensis Dugand, 1943 - E Andes in Boyacá and Cundinamarca, NC Colombia.

C. c. parvircristatus (Gould, 1843) - C Colombia (E slope of E Andes in Boyacá and Cundinamarca, through Meta and llanos) to SC Venezuela (NW Bolívar and N Amazonas).

C. c. horvathi (Madarász, 1904) - Andes of Mérida, NW Venezuela.

C. c. cristatus (Gilliland, 1940 - Portuguesa and Barinas, WC Venezuela.

C. c. moqueyensis (Hartert, 1894) - Sucre, N Monagas and N Anzoátegui, NE Venezuela.

C. c. sonnini (Temminck, 1815) - Carabobo and Caracas, NC Venezuela, S through Orinoco Basin and Guianas to N Brazil.

Introduced (*sonnini*) to Mustique, Grenadines, St Thomas and Virgin Is.

Descriptive notes. 18-21.5 cm; male 132-153 g, female 131-141 g (Surinam). Prominent crest separates from congeners, although size variable with race; crown and crest white to buff. Overall coloration mottled grey, brown and black. Side of head, throat and eyeline rufous; hindneck and ring around throat white with black and cinnamon spots; back and rump mottled grey and brown; wing feathers with buff margins; breast and belly cinnamon with black, white and buff spots. Bill black, legs horn. Female has shorter, darker brown crest; plumage mottled brown and buff, with black and brown streaks. Immature spotted

brown and white on breast and belly; greater primary coverts tipped buff. Races differ mainly in tone of plumage and length of crest; also some variation in size.

Habitat. Arid lowlands, and locally into subtropical zone, using thickets, woodland edges, savanna, roadsides and embankments; also agricultural fields (of rice and sugarcane, or pastures). Generally under 1500 m, but up to 3200 m in Colombia.

Food and Feeding. Mainly seeds, but also insects during wet season in Venezuela. Most important plants include *Euphorbia*, *Hyptis*, Mimosaceae, *Phaseolus*, *Brachiaria*, *Digitaria*, *Paspalum* and *Hachelochloa*; also feeds on sesame and sorghum. In Brazil, adapted to life alongside humans and will come to houses to feed.

Breeding. Apr/May-Oct/Nov, corresponding to wet season in Venezuela; adults in breeding condition Jul-Sept in Colombia, where chick seen in Feb. 8-16 eggs in Venezuela; up to 15 eggs in Colombia. Eggs cream-coloured, often heavily spotted or blotched with brown; size averages 40 x 30 mm. Incubation 22-23 days.

Movements. Presumably sedentary. Pairs and coveys up to 12 birds in Surinam, and of 10-15 birds in Venezuela.

Status and Conservation. Not globally threatened. Mace-Landé: Safe. Status not well known; total population might number over 1,000,000 birds. Apparently common in many areas, and range expansion reported. Very common in some major river valleys of Colombia. Has recently spread into lowlands of Golfo Dulce, in SW Costa Rica. However, highland races in Colombia uncommon and local. Species has generally benefited from activities of humans, especially from clear-cutting of forest and development of agriculture. Potential threats include pesticides, in agricultural areas, and hunting.

Bibliography. Blake (1977), Borrero (1972), Darlington (1931), Espinoza (1982, 1983), Fjeldså & Krabbe (1990), Gines & Alveledo (1958), Haverschmidt (1968), Hilty & Brown (1986), Johnsgard (1988), Mendez (1979), Mendoza (1982a, 1982b), Meyer de Schauensee (1964), Meyer de Schauensee & Phelps (1978), Miller (1963), Monroe (1968), Morales (1977a, 1977b, 1980), Morales & Pacheco (1976), Peters (1934), Pinto (1964), Ridgely & Gwynne (1989),

Dark-backed Wood-quail (*Odontophorus melanonotus*).

Ridgway & Friedmann (1946), Ruschi (1979), Schäfer & Phelps (1954), Schönwetter (1967), Sick (1985a, 1993), Snyder (1966), Stiles & Skutch (1989), Tostain *et al.* (1992), Wetmore (1927, 1963, 1965).

Genus *ODONTOPHORUS* Vieillot, 1816

14. Marbled Wood-quail

Odontophorus gujanensis

French: Toco de Guyane German: Marmorwachtel Spanish: Corcovado Común

Taxonomy. *Tetrao gujanensis* Gmelin, 1789, Cayenne.

Eight subspecies recognized.

Subspecies and Distribution.

O. g. castigatus Bangs, 1901 - SW Costa Rica and (formerly) W Panama.

O. g. marmoratus (Gould, 1844) - E Panama to N Colombia and NW Venezuela.

O. g. gujanensis (Gmelin, 1789) - SE Venezuela, Guianas and Brazil (S to Mato Grosso) and extreme N Paraguay.

O. g. medius Chapman, 1929 - S Venezuela and NW Brazil.

O. g. buckleyi Chubb, 1919 - base of E Andes of Colombia, E Ecuador and N Peru.

O. g. rufogularis Blake, 1959 - upper reaches of R Yavari, NE Peru.

O. g. pachyrhynchus Tschudi, 1844 - E Peru and possibly also W Bolivia.

O. g. simonsi Chubb, 1919 - E Bolivia.

Descriptive notes. 23-29 cm; male 313-380 g, female 298 g. Bare eye-ring of red or orange skin distinctive. Plumage lacks any striking patterns; overall coloration brown and grey, although highly variable. Crown and crest reddish brown with dark vermiculations; sides of head and throat chestnut, rufous or grey. Back and rump brown or grey with black vermiculations; scapulars and upperwing-coverts brown or grey, with black and buff spots; breast and belly grey, brown or medially tawny, with black and white barring or spots. Bill and legs bluish black or grey. Female slightly smaller, but otherwise similar. Imma-

ture has less vermiculation and orange-red bill. Races vary somewhat in general coloration, especially of sides of head.

Habitat. Lowland tropical and subtropical forest up to 1800 m. Found on forest floor in rain forest and in old second growth.

Food and Feeding. Berries and Myriopoda (Diplopoda) in Surinam; starchy seeds and invertebrates, e.g. millipedes, ants, cockroaches, spiders and beetles, in Panama; and dried bananas and possibly insects in Costa Rica.

Breeding. Nests found in Jan, Apr and Jun; breeding female collected in Costa Rica in Aug. Duetting reported. Nests are chambered with roofs of dead vegetation, apparently placed at base of trees or amongst roots; nest 28 cm long, 13 cm wide. Clutch size of 4 eggs (2 nests); incubation 24-28 days, apparently only by female. Chicks seen with coveys of 5-6 adults. Eggs white or white with brown spots, measuring 35.0-40.5 x 26.6-28.6 mm.

Movements. Presumably sedentary. Groups of 6-8 birds, possibly referring to families.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Very little information available; total population may number over 1,000,000 birds, but possibly declining. Reported to be common in Amazon region of SE Peru, but possibly uncommon elsewhere. Apparently rare to locally common in Panama, although scarce near human settlement due to hunting. Scarce in Costa Rica, except where forest is intact. Race *castigatus* probably extirpated in Panama, and found only in restricted area in Costa Rica. Major threats include deforestation and hunting; however, with extensive distribution, probably more secure than most *Odontophorus*.

Bibliography. Blake (1977), Borrero (1972), Chapman (1917, 1926), Dubs (1992), Gines & Aveledo (1958), Havensmidt (1968), Hilty & Brown (1986), Johnsgard (1979, 1988), Mendez (1979), Meyer de Schauensee (1964), Meyer de Schauensee & Phelps (1978), Miller (1963), Parker *et al.* (1982), Petrides (1942), Phelps & Phelps (1958), Pinto (1964), Remsen & Traylor (1989), Ridgely & Gwynne (1989), Ridgway & Friedmann (1946), Ruschi (1979), Sick (1985a, 1993), Skutch (1947b, 1983a), Slud (1964), Snyder (1966), Stiles & Skutch (1989), Terborgh *et al.* (1984), Tostain *et al.* (1992), Wetmore (1965).

15. Spot-winged Wood-quail

Odontophorus capueira

French: Toco uru German: Capueirawachtel Spanish: Corcovado Urú

Taxonomy. *Perdix capueira* Spix, 1825, Rio de Janeiro and Minas Gerais.

Validity of race *plumbeicollis* questionable. Two subspecies recognized.

Subspecies and Distribution.

O. c. capueira (Spix, 1825) - E Brazil, E Paraguay, extreme NE Argentina.

O. c. plumbeicollis Cory, 1915 - NE Brazil

Descriptive notes. 26.5-29 cm; estimated weight of male 457 g, of female 396 g. Bright red bare eye-ring and eyelid. Sides of head, malar region, chin, throat, breast and belly plain grey; overall colour brown to grey. Crest and crown chestnut, foreneck and supercilium tawny. Back brown, with white shaft streaks; scapulars chestnut, with white shaft streaks; rump tawny with black spots. Light-feathers black with white spots. Bill black, legs grey-black. Female similar, but slightly more slender. Immature has wider shaft streaks on back; black spots on rump coarser, breast grey and belly reddish brown. Race *plumbeicollis* has

underparts paler with buff tone; supercilium and white shaft streaks on upper back are rather less prominent.

Habitat. Atlantic lowland tropical forest, including second growth forest. Found on forest floor.

Food and Feeding. Berries, especially *Phytolacca decandra*; also nuts of *Araucaria* on forest floor.

Breeding. Aug-Nov. Nests on ground, sometimes in armadillo holes. In captivity: domed nest of 40 x 50 cm was constructed; 5 eggs laid; eggs hatched after incubation period of 26-27 days. Incubation reported as 18-19 days in wild. Eggs white, often stained yellow or red; average size 40.1 x 29.1 mm.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Very little information available; total population might number under 50,000 birds, and declining. Much reduced in interior of Brazil, and now restricted mainly to protected Atlantic coastal forests; populations of NE Brazil appear to be those most at risk. Reported common in some places where habitat protected. Major threats include deforestation and hunting. Very few recent records from Argentina and Paraguay. Extensive surveys required. Some 26 birds known to be held in captivity.

Bibliography. Alderton (1992), Blake (1977), Carvalho (1940), Dubs (1992), Flieg (1970b), Johnsgard (1979, 1988), de Magalhães (1977), de la Peña (1992), Pinto (1952a, 1964), Ruschi (1979), Sick (1985a, 1993).

16. Black-eared Wood-quail

Odontophorus melanotis

French: Toco à face noire German: Schwarzhöhrwachtel Spanish: Corcovado Orejinegro

Taxonomy. *Odontophorus melanotis* Salvin, 1865, Tucurrique, Costa Rica.

Often considered race of *O. erythrops*. Birds of Panama formerly awarded separate race, *coloratus*. Two subspecies recognized.

Subspecies and Distribution.

O. m. verecundus Peters, 1929 - Caribbean slope of Honduras.

O. m. melanotis Salvin, 1865 - SE Honduras, Nicaragua and Caribbean coast of Costa Rica and Panama.

Descriptive notes. 22-28 cm; estimated weight of male 340 g, of female 329 g. Very similar to *O. erythrops*, but lacks white jugular band. Bare ring around eye purple; overall coloration can be dark brown or blackish with rufous breast. Crown, crest and face chestnut; throat and foreneck brownish black. Back and rump black or olive with cinnamon vermiculations; scapulars black, or olive with black spots; belly tawny. Bill black, legs blue-black. Female similar, but sides of head darker and duller chestnut, and eye-ring blue-black. Immature similar, but with duller crest; back has white or buffy shaft streaks, belly spotted and

barred with black. Race *verecundus* has upperparts greyer.

Habitat. Tropical and lower subtropical forests at 450-1600 m, locally to sea-level. Found on forest floor in virgin forest and in thick second growth.

Food and Feeding. No information available.

Breeding. Nest found in excavation between buttresses of tree in Costa Rica. Clutch 4 eggs. Eggs cream or white with brown spots, averaging 37.6 x 27.9 mm.

Movements. Presumably sedentary. Found singly, in pairs, or in small groups; groups of up to 10 birds in Costa Rica.

Status and Conservation. Not globally threatened. Mace-Land: possibly Safe. Total population might number under 50,000 birds, and declining. Restricted range; very little information available. Becoming scarce and local in Costa Rica. Major threats include deforestation, and possibly hunting. Extensive surveys required.

Bibliography. Alderton (1992), Blake (1977), Howell (1971), Johnsgard (1979, 1988), Mendez (1979), Monroe (1968), Ridgely & Gwynne (1989), Ridgway & Friedmann (1946), Slud (1964), Stiles & Skutch (1989), Wetmore (1965).

17. Rufous-fronted Wood-quail

Odontophorus erythrops

French: Toco à front roux German: Rotstirn wachtel Spanish: Corcovado Frentirrojo

Other common names: Rufous-breasted Wood-quail

Taxonomy. *Odontophorus erythrops* Gould, 1859, Pallatanga, Ecuador.

Often considered to include *O. melanotis*. May be conspecific with three other species, *O. speciosus*, *O. hyperythrus* and *O. melanotus*. At other extreme, race *parambae* has been considered distinct species. Two subspecies normally recognized.

Subspecies and Distribution.

O. e. parambae Rothschild, 1897 - Pacific slope of Colombia S to W Ecuador; possibly also E Panama.

O. e. erythrops Gould, 1859 - SW Ecuador.

Descriptive notes. 23-28 cm; estimated weight of male 340 g, of female 329 g. Very similar to *O. melanotis*, but has white jugular band. Bare ring around eye purple; overall coloration can be dark brown or blackish with rufous breast. Crown, crest and face rufous; throat and foreneck black. Back and rump black or olive, with cinnamon vermiculations; scapulars black or olive with black spots; breast and belly dark rufous. Bill black, legs blue-black. Female similar, but sides of head darker and duller chestnut, and eye-ring blue-black. Immature similar, but with duller crest; back with white or buffy shaft streaks, belly

spotted and barred with black. Race *parambae* somewhat darker.

Habitat. Humid lowland tropical forest at elevations under 1600 m. Found on forest floor.

Food and Feeding. No information available.

Breeding. No information available.

Movements. Presumably sedentary. One group of 7 individuals observed.

Status and Conservation. Not globally threatened. Mace-Lande: probably Safe. Very little information available; total population might number under 500,000 birds; apparently declining. Common in some areas in Colombia. Major threats include deforestation, and possibly hunting. Some cause for concern in W Andes of Colombia, due to deforestation at lower altitudes; most protected areas and parks are concentrated at higher elevations. Extensive surveys required.

Bibliography. Alderton (1992), Blake (1977), Borrero (1972), Carriker (1910), Chapman (1926), Hilty & Brown (1986), Johnsgard (1979, 1988), Mendez (1979), Meyer de Schauensee (1964), Negret (1991), Ridgway & Friedmann (1946), Robbins *et al.* (1985), Wetmore (1965).

18. Black-fronted Wood-quail

Odontophorus atrifrons

French: Toco à front noir **German:** Schwarzstirnachtel **Spanish:** Corcovado Carinegro

Taxonomy. *Odontophorus atrifrons* Allen, 1900, Santa Marta, Colombia.

May be conspecific with four other species, *O. strophium*, *O. columbianus*, *O. leucolaemus* and *O. dialeucos*. Three subspecies recognized.

Subspecies and Distribution.

O. a. atrifrons Allen, 1900 - Santa Marta Mts, NE Colombia.

O. a. variegatus Todd, 1919 - N end of E Andes, NE Colombia.

O. a. navai Aveledo & Pons, 1952 - Perijá Mts, NE Colombia and NW Venezuela.

Descriptive notes. 25-27 cm; estimated weight of male 311 g, female 298 g. Black forehead, face and throat distinctive; crown rufous brown. Overall coloration blackish brown. Back grey with black vermiculation, becoming browner towards the rump; wings mottled with cinnamon and black; flight-feathers tipped black, but showing white of feather shafts. Bill black, legs dusky horn coloured. Female similar, but underparts more rufescent. Immatures have brownish red upper mandible, and black feathers on throat, tipped with tawny olive. Races differ in extent of black and in overall coloration.

Habitat. Montane tropical and subtropical forests at 1200-3100 m. Found on forest floor.

Food and Feeding. No information available.

Breeding. Male in breeding condition and female laying in Aug; immature found during Jul in Perijá Mts, NW Venezuela.

Movements. Presumably sedentary. Occurs in groups of up to 10 individuals.

Status and Conservation. Not globally threatened. Mace-Lande: possibly Vulnerable. Currently considered near-threatened. Total population might number under 10,000 birds, and declining. Restricted range; very little information available. Possibly common in large protected area in Santa Marta Mts, NE Colombia. Race *navai* protected in Sierra de Perijá National Park, NW Venezuela. Major threats include deforestation, mineral extraction, and possibly hunting. Extensive surveys required.

Bibliography. Alderton (1992), Blake (1977), Borrero (1972), Fjeldsá & Krabbe (1990), Gines & Aveledo (1958), Hilty & Brown (1986), Johnsgard (1979, 1988), Meyer de Schauensee (1964), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1958), Schwartz & Lenino (1984), Todd & Carriker (1922).

19. Chestnut Wood-quail

Odontophorus hyperythrus

French: Toco marron **German:** Kastanienachtel **Spanish:** Corcovado Castaño

Taxonomy. *Odontophorus hyperythrus* Gould, 1858, Santa Fé de Bogotá, Colombia.

May be conspecific with three other species, *O. speciosus*, *O. erythrops* and *O. melanotus*. Possibly most closely related to *O. speciosus*. Some evidence of differences in plumage colour between populations of W and C Andes. Monotypic.

Distribution. Endemic to C and W Andes of Colombia.

Descriptive notes. 25-28.5 cm; estimated weight of male 392 g, female 351 g. Overall coloration chestnut to dark brown; feathers around eye and ear-coverts white. Head chestnut, foreneck and breast rufous; back, rump and wings mainly brown; upperwing-coverts spotted white; back and rump with fine black vermiculations. Bill black, legs bluish grey. Female similar, but much of breast and belly dark grey. Juvenile similar to adults, but upperwing-coverts and scapulars tipped buff; orange-red tip to bill.

Habitat. Montane subtropical forests at 1600-2700 m, including second growth and forest borders; normally found on forest floor. Some evidence of use of coffee plantations with shade trees. Has been seen roosting in trees.

Food and Feeding. Consumes seeds and berries, and possibly also insects. Forages by scratching in leaf litter for roots, seeds and fruits which have fallen from trees.

Breeding. Generally unknown; laying thought to be during Apr-May, based on gonad development.

Movements. Presumably sedentary. Groups of 3-9 individuals reported.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. Currently considered near-threatened. Total population may number under 10,000 birds, and in decline. Restricted range; very little information available. Populations occur in some protected areas including Las Orquideas, Los Nevados, Cueva de los Guácharos, Munchique and Farallones National Parks. Possibly common at Acaime, in Salento. Major threats include deforestation and possibly hunting. Populations of C Andes apparently more at risk, as more intensive deforestation has resulted in fragmentation and isolation of populations; some populations do appear to persist in small forest fragments. In W Andes, some conversion of forest habitat to pine plantations, with unknown effects on species. Survey work required.

Bibliography. Alderton (1992), Blake (1955, 1977), Borrero (1972), Chapman (1917), Collar & Andrew (1988), Fjeldsá & Krabbe (1990), Hilty (1985), Hilty & Brown (1986), Johnsgard (1979, 1988), Meyer de Schauensee (1964), Miller (1963), Negret (1991), Renjifo (1988), Uribe (1986).

20. Dark-backed Wood-quail

Odontophorus melanotus

French: Toco à dos noir **German:** Schwarzüückenachtel **Spanish:** Corcovado Dorsioscuro
Other common names: Black-backed Wood-quail

Taxonomy. *Odontophorus melanotus* Gould, 1860, Ecuador.

May be conspecific with three other species, *O. hyperythrus*, *O. erythrops* and *O. speciosus*. Probably most closely related to *O. speciosus*. Monotypic.

Distribution. Mountains of NW Ecuador and SW Colombia.

Descriptive notes. 24-27 cm; estimated weight of male 226 g, of female 220 g. Overall colour brownish black; throat and breast reddish chestnut, becoming darker below; brownish black eye-ring. Crown and sides of head, back, rump, wings and belly brownish black with fine chestnut vermiculations. Bill black, legs brownish black. Female identical. Immature dull brown, with reddish bill and greenish grey legs.

Habitat. Lower subtropical forest at altitudes of 1200-1500 m.

Food and Feeding. No information available.

Breeding. No information available.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. Mace-Lande: possibly Vulnerable. Currently considered near-threatened. Total population might number under 10,000 birds, with trends unknown. Restricted range; very little information available. Recently found to be common in well protected reserve of La Planada, SW Colombia. Major threats include deforestation, and possibly hunting. Survey work required.

Bibliography. Alderton (1992), Blake (1977), Chapman (1926), Fitzpatrick & Willard (1982), Hilty & Brown (1986), Johnsgard (1979, 1988), Robbins (1981), Schönwetter (1967).

21. Rufous-breasted Wood-quail

Odontophorus speciosus

French: Toco à poitrine rousse German: Rotbrustwachtel Spanish: Corcovado Pechirrufo

Taxonomy. *Odontophorus speciosus* Tschudi, 1843, Peru.

May be conspecific with three other species, *O. hyperythrus*, *O. erythrops* and *O. melanotus*. Possibly most closely related to *O. hyperythrus*. Three subspecies recognized.

Subspecies and Distribution.

O. s. soederstroemii Lönnberg & Rendahl, 1922 - E & S Ecuador.

O. s. speciosus Tschudi, 1843 - EC Peru.

O. s. loricae Todd, 1932 - SE Peru to E Bolivia.

Descriptive notes. 25-26.5 cm; estimated weight of male 332 g, of female 302 g. Breast and belly rufous chestnut; crown dark brown, bordered by black on sides of head and neck, and on throat. Overall coloration brown and chestnut. Ear-coverts brown; white line extending from bill over eye down side of neck; bare eye-ring bluish black. Back and rump brown, with fine black vermiculations and white feather shafts; upwing-coverts spotted with either black or white, and with white feather shafts. Bill black, legs bluish black. Female similar, but rufous chestnut ends on upper breast, and replaced by grey on lower breast and belly. Immature has sides of head, chin and throat chestnut, with dusky margins; white stripe on head narrower; back and rump with reduced shaft stripes; longer scapulars tipped with rufous buff. Races separated on coloration, especially of crown and sides of head.

Habitat. Tropical lowland forest at elevations under 1700 m. Found on forest floor.

Food and Feeding. No information available.

Breeding. No information available.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Very little information available; total population might number over 500,000 birds, and possibly stable. Reported to be uncommon in Peru, but fairly common in Podocarpus National Park, S Ecuador. Possible threats include deforestation and perhaps hunting; however, probably more secure than most *Odontophorus*, due to remote distribution. Surveys and research required.

Bibliography. Alderton (1992), Blake (1977), Chapman (1926), Davis (1986), Johnsgard (1979, 1988), Parker *et al.* (1982), Raethel (1988), Remsen & Traylor (1989), Robbins (1981), Terborgh & Weske (1975), Traylor (1958).

22. Tacarcuna Wood-quail

Odontophorus dileucos

French: Toco de Panama German: Tacarcunawachtel Spanish: Corcovado del Tacarcuna

Taxonomy. *Odontophorus dileucos* Wetmore, 1963, Darién, Panama.

May be conspecific with four other species, *O. columbianus*, *O. atrifrons*, *O. leucolaemus* and *O. strophium*. Probably most closely related to *O. strophium*. Monotypic.

Distribution. Endemic to extreme E Panama and adjacent Chocó, NW Colombia.

Descriptive notes. 22-25 cm; estimated weight of male 264 g, of female 258 g. Crown black; separated from black throat by white supercilium, lores and chin. Overall coloration dark or olive-brown. Sides and back of neck cinnamon; back and rump olive brown, with fine black vermiculation; breast and belly chestnut, with fine white specks. Bill black, legs brownish black. Female similar, but paler. Immature similar to female, but with less white on chin, and broader black band on foreneck.

Habitat. Subtropical forest at 1050-1450 m. Found on forest floor.

Food and Feeding. No information available.

Breeding. Virtually no information; immature collected in June.

Movements. Presumably sedentary. Occurs in pairs or in groups of up to 8 individuals.

Status and Conservation. Not globally threatened. Mace-Land: possibly Safe. Currently considered near-threatened. Total population might number under 50,000 birds. Restricted range; very little information available. Threats may include deforestation and hunting. Additional surveys required in Chocó, NW Colombia, to determine status of recently discovered population. Research required.

Bibliography. Alderton (1992), Blake (1977), Hilty & Brown (1986), Johnsgard (1979, 1988), Mender (1979), Pearman (1993b), Ridgely & Gwynne (1989), Robbins (1981), Rodríguez (1982), Wetmore (1963, 1965).

23. Gorgeted Wood-quail

Odontophorus strophium

French: Toco à miroir German: Kragenwachtel Spanish: Corcovado Gorgiblanco

Taxonomy. *Oryx (Odontophorus) strophium* Gould, 1844, Colombia.

May be conspecific with four other species, *O. columbianus*, *O. atrifrons*, *O. leucolaemus* and *O. dileucos*. Monotypic.

Distribution. Endemic to W slope of E Andes of Colombia, where restricted to two areas in departments of Santander and Cundinamarca.

Descriptive notes. 25.5-27 cm; estimated weight 302 g. Black band across foreneck, separating white throat from white upper breast; crown and eyeline brown; cheeks and supercilium white. Overall coloration brownish. Lower breast brown, with rows of white spots ending before rufous belly; back mottled with thin white streaks; scapulars spotted black. Bill and legs black. Female

similar, but grey below, and rows of white spots on breast much reduced. Immature has more brownish grey on breast and sides; white spots on breast reduced to streaks.

Habitat. Montane temperate and subtropical forests at 1500-2050 m, especially those dominated by *Quercus humboldtii*. Found on forest floor. Will use second growth forest.

Food and Feeding. Feeds on fruits and seeds, including *Quercus humboldtii*, *Trigonobalanus*, *Cavendishia guatapiensis* and *C. cf. nitida*, *Macleania rupestris*, *Miconia theaezans*, *Myrica pubescens*, *Rapanea ferruginea*, *Ficus boyacensis*, and *Norantea mista*; also known

to take arthropods.

Breeding. Breeding season apparently coincides with peaks of annual rainfall during Mar-May and Sept-Nov (based on several adults collected in breeding condition, and immatures collected in Dec). No further information available.

Movements. Presumably sedentary. Occurs in small groups of 1-3 birds.

Status and Conservation. VULNERABLE/RARE. Mace-Land: Endangered. Total population thought to number under 2500 birds, and still declining. Restricted range, encompassing area only c. 280 km long at maximum; very little information available. Major threats include deforestation, and hunting. Cachalú Wildlife Sanctuary of 10,000 ha established at Guanentá-Alto Río Fonce in temperate forests in vicinity of Virolín, Santander; efforts under way to consolidate reserve and set up research projects. No recent evidence of populations in Cundinamarca, where few forest patches remain, and species last recorded in 1923.

Bibliography. Alderton (1992), Blake (1977), Borrero (1972), Brooke (1988), Chapman (1917), Collar & Andrew (1988), Collar *et al.* (1992), Fjeldså & Krabbe (1990), Hilty (1985), Hilty & Brown (1986), Johnsgard (1979, 1988), King (1978/79), Kuroda (1970), Meyer de Schauensee (1964), Romero-Zambrano (1983).

24. Venezuelan Wood-quail

Odontophorus columbianus

French: Toco du Venezuela German: Venezuelawachtel Spanish: Corcovado Venezolano

Taxonomy. *Odontophorus columbianus* Gould, 1850, Caracas, Venezuela.

May be conspecific with four other species, *O. strophium*, *O. atrifrons*, *O. leucolaemus* and *O. dileucos*. Monotypic.

Distribution. Endemic to NC Venezuela.

Descriptive notes. 28-30 cm; estimated weight of male 343 g, of female 336 g. Overall coloration reddish brown with pale streaks on upwing-coverts; throat and chin white with black streaks. Large white droplets on breast, belly and flanks. Bill black, legs dark grey. Female lacks pale streaks on closed wing and has much reduced white droplets on underside. Juvenile shows lesser development of pale streaks and white spots; bill orange.

Habitat. Montane subtropical cloud forests at altitudes of 1100-2000 m. Found on forest floor. Has been seen roosting above ground on palm fronds.

Food and Feeding. Little information. Consumes seeds, fruits, insects and worms. Forages by scratching litter to expose soil; also scrapes into soil, apparently to feed on fleshy roots.

Breeding. From Mar perhaps to end of Jul. One chambered nest with roof of vegetation found at base of palms. One clutch of 6 eggs. Eggs white, measuring 40.5-43.5 mm x 29.0-29.5 mm. Incubation 30 days.

Movements. Presumably sedentary. During Jan, singles, pairs and groups of up to 9 birds observed.

Status and Conservation. Not globally threatened. Mace-Land: possibly Vulnerable. Currently considered near-threatened. Total population might number under 10,000 birds, and declining. Restricted range; very little information available. Populations occur in some protected areas, including San Esteban National Park. Possibly still common in some protected areas; more than a dozen groups recorded at Rancho Grande, Henri Pittier National Park, during survey in Jan 1994. Major threats include deforestation, hunting and urbanization. Research and surveys required.

Bibliography. Alderton (1992), Blake (1977), Fjeldså & Krabbe (1990), Gines & Alveledo (1958), Johnsgard (1979, 1988), Laskowski *et al.* (1992), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1958), Schäfer (1953b), Schäfer & Phelps (1954), Schwartz & Lentino (1984), Zimmer & Phelps (1954).

25. Black-breasted Wood-quail

Odontophorus leucolaemus

French: Toco à poitrine noire German: Weißkehlwachtel Spanish: Corcovado Pechinegro
Other common names: White-throated Wood-quail

Taxonomy. *Odontophorus leucolaemus* Salvin, 1867, Cordillera de Tolé, Veraguas, Panama.

May be conspecific with *O. strophium*, *O. atrifrons*, *O. columbianus* and *O. dileucos*. Proposed race *smithianus*, from Dota Mts of Costa Rica, generally considered a melanistic morph. Monotypic.

Distribution. NE, E & C highlands of Costa Rica S to W Panama. Most records on Caribbean slope.

Descriptive notes. 22-25.5 cm; estimated weight of male 226 g, of female 220 g. Crown, crest and ear-coverts black; large white patch on throat; neck and breast black with dull-white feather tips. Overall coloration dark brown. Belly brown with fine black vermiculations. Iris brown, bill black, legs dark grey. Sexes similar. Juvenile browner on breast; bill brown or red. Population of Dota Mts (Costa Rica) smaller and almost entirely black.

Habitat. Tropical and subtropical forests at 800-1850 m, including second growth and forest borders, but mostly in interior of forest. Found on forest floor, generally in thickest vegetation, e.g. in scrub and amongst vines.

Food and Feeding. Virtually no information available; may take plant matter, supplemented with insects.

Breeding. Nests found in Jun. Nests in heavily shaded second growth along bank of stream; nest is hollow in leaf litter, measuring 24 x 13 cm. Clutches of 5 eggs. Eggs white, but become stained brown; 44.5 x 28.7 mm. Incubation said to be 16-17 days. Apparently groups of adults guard nest-site, but do not assist with incubation. **Movements.** Presumably sedentary. Moves about in pairs or groups of 10-15 birds. **Status and Conservation.** Not globally threatened. Mace-Land: possibly Safe. Currently considered near-threatened. Total population might number under 50,000 birds; perhaps declining. Restricted range; very little information available.

Generally rare in Costa Rica, although locally common; most records from Panama are old. Isolated population in Dota Mts, Costa Rica. Reported to be common at Monteverde Reserve, Puntarenas, Costa Rica. Major threats possibly include deforestation and hunting. Extensive surveys required.

Bibliography. Alderton (1992), Blake (1958, 1977), Carriker (1910), Johnsgard (1979, 1988), McDonald & Winnett-Murray (1989), Mendez (1979), Ridgely & Gwynne (1989), Ridgway & Friedmann (1946), Slud (1964), Stiles & Skutch (1989), Wetmore (1965)

26. Stripe-faced Wood-quail

Odontophorus balliviani

French: Toco de Ballivian

Spanish: Corcovado Enmascarado

German: Streifengesichtwachtel

Taxonomy. *Odontophorus balliviani* Gould, 1846, Cochabamba, Bolivia. Monotypic.

Distribution. Endemic to E Andes of SE Peru, and N & W Bolivia, in La Paz and Cochabamba.

Descriptive notes. 26-28 cm; estimated weight of male 311 g, of female 324 g. Crest and crown chestnut bordered by buff; eye-ring red, with black stripe behind eye extending along edge of nape. Overall coloration brown. Buff throat, with lines of white streaks becoming diamond-shaped spots; bordered by black on breast, belly and flanks. Ground colour of breast and belly brown; back and rump brown, mottled with black vermiculations; scapulars and wings brown, with black and chestnut spots. Bill black, legs dark lead. Female very similar, but may have fewer white streaks on throat. Immature not described.

Habitat. Montane subtropical forest at 2000-3000 m; found in heavy forest, stunted cloud forest, clearings and boggy meadows.

Food and Feeding. No information available.

Breeding. Egg size 38 x 26.8 mm.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. Mace-Land: possibly Safe. Total population might number under 50,000 birds; perhaps in decline. Restricted range; very little information available. Threats possibly include deforestation, urbanization and agriculture. Rarely reported in wild, but inhabits areas with difficult access. Reported to be uncommon in Peru. Surveys required to evaluate populations and delimit distribution.

Bibliography. Alderton (1992), Blake (1977), Fjeldså & Krabbe (1990), Johnsgard (1979, 1988), Parker *et al.* (1982), Remsen & Traylor (1989), Robbins (1981), Schönwetter (1967).

27. Starred Wood-quail

Odontophorus stellatus

French: Toco étoilé

German: Sternwachtel

Spanish: Corcovado Estrellado

Taxonomy. *Odontophorus stellatus* Gould, 1843, Brazil. Monotypic.

Distribution. Upper Amazon region: extreme E Ecuador, E Peru and W Brazil (S of Amazon, E to Rio Madeira) S to NW & NE Bolivia. Possibly also occurs in extreme SE Colombia.

Descriptive notes. 24-26 cm; estimated weight of male 358 g, of female 315 g. Large crest rufous chestnut; head and neck ash grey; yellow eye-ring; sometimes has white flecking on supercilium. Overall colour brown to rufous. Back brown to rufous, fading to buff on rump, with fine black vermiculations; scapulars with black spots and white feather shafts; upperwing-coverts tipped white. Breast chestnut-rufous, but paler medially; sparse white diamonds, like teardrops, on sides of breast. Bill and legs black. Female similar, but crest darker brown or brownish black. Immature similar, but bill reddish orange to yellow.

Habitat. Lowland tropical forest.

Food and Feeding. No information available.

Breeding. No information available.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Very little information available; total population might number over 750,000 birds. Reported to be fairly common in Peru. Possible threats include deforestation and possibly hunting; however, isolated distribution probably makes it more secure than most other members of *Odontophorus*. Research required.

Bibliography. Alderton (1992), Blake (1977), Chammán (1921, 1926), Gysels-Simpe (1945, 1951), Hilty & Brown (1986), Johnsgard (1979, 1988), Parker *et al.* (1982), Pinto (1964), Remsen & Traylor (1989), Robbins (1981), Rosen (1979), Siek (1985a), Terborgh & Weske (1975), Terborgh *et al.* (1984), Traylor (1958).

28. Spotted Wood-quail

Odontophorus guttatus

French: Toco tacheté

German: Tropfenwachtel

Spanish: Corcovado Goteado

Taxonomy. *Ortyx guttatus* Gould, 1838, Bay of Honduras = Belize.

Proposed race *matudae* known only from one location, and not normally considered valid. Monotypic. **Distribution.** S Mexico (S México State to Yucatán) and Belize through N Guatemala and W & C Honduras into bordering Nicaragua; two further small populations, one in N Costa Rica, and one in S Costa Rica and adjacent W Panama.

Descriptive notes. 23-26.5 cm; average male 300 g, female 288 g. Polymorphic in both sexes, with brown and red morphs. Brown morph has crown blackish brown with orange crest; sides of head and neck cinnamon; throat black with white streaks; breast and belly brown with white spots, round or like teardrops. Overall coloration brown. Back and rump dark brown, with white feather shafts and black and buff mottling. Bill and legs dull green or black. Red morph differs mainly in reddish brown breast. Female similar, but crest blackish. Immature has rusty red crest, and breast markings more in form of streaks than of spots; bill orange-red.

Habitat. Tropical and subtropical montane forests at 500-3000 m, although locally to lower elevations, e.g. to 100 m in Costa Rica. Found on forest floor with sparse understorey and also older second growth. In Costa Rica reported from forest edge and up to tree-line.

Food and Feeding. Small bulbs, rootlets, flesh of large nuts and insects, including pupae and larvae (of Diptera, Coleoptera). Food obtained by scratching forest litter in circles up to 30 cm in diameter to reach bare ground. In captivity, will eat fruits, softened and hard grain, and dried beans.

Breeding. Nesting possibly May-Jun in Yucatán, Mexico; young chicks in May in Chiapas, S Mexico, and Guatemala; male in breeding condition from Belize in Mar; "well grown young" collected in Mexico during Dec. Nests on ground. Eggs white, sometimes with brown spots; size 39.2-40.5 x 28.5-29.7 mm.

Movements. Presumably sedentary; might undertake altitudinal migrations in Costa Rica. Circulates in coveys of 6-20 birds in Mexico, but only 1-4 just prior to breeding; groups of 4-10 birds in Costa Rica; larger coveys are apparently not family groups.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Very little information available; total population might number under 500,000 birds, possibly declining. Apparently common in many parts of range. Major threats include deforestation, and possibly hunting. Although found in small and rather isolated populations, apparently more capable of withstanding habitat destruction and fragmentation than other members of *Odontophorus*.

Bibliography. Alvarez del Toro (1952), Binford (1989), Blake (1953, 1958, 1977), Briggs (1954), Brodtkorb (1943), Carriker (1910), Davis (1972), Edwards (1989), Edwards & Lea (1955), Griscom (1932), Johnsgard (1973, 1979, 1988), Land (1970), Leopold (1959), Lowery & Dalquest (1951), Mendez (1979), Monroe (1968), Paynter (1955), Pielka (1948), Ridgely & Gwynne (1989), Ridgway & Friedmann (1946), Russell (1964), Saunders *et al.* (1950), Slud (1964), Smithe (1966), Stiles & Skutch (1989), Traylor (1941), Van Tyne (1935), Wetmore (1965).

Genus *DACTYLORTYX* Ogilvie-Grant, 1893

29. Singing Quail

Dactylortyx thoracicus

French: Colin chanteur

German: Singwachtel

Spanish: Colin Cantor

Other common names: Long-toed Quail/Partridge

Taxonomy. *Ortyx thoracicus* Gambel, 1848, Jalapa, Veracruz, Mexico.

As many as ten races of doubtful validity. Seventeen subspecies normally recognized.

Subspecies and Distribution.

D. t. pettingilli Warner & Harrell, 1957 - SE San Luis Potosí and SW Tamaulipas, CE Mexico.

D. t. thoracicus (Gambel, 1848) - NE Puebla and C Veracruz, EC Mexico.

D. t. devius Nelson, 1898 - Jalisco, WC Mexico.

D. t. melodus Warner & Harrell, 1957 - C Guerrero, SC Mexico.

D. t. ginetensis Warner & Harrell, 1957 - SE Oaxaca and W Chiapas, S Mexico.

D. t. edwardsi Warner & Harrell, 1957 - W Chiapas, S Mexico.

D. t. chiapensis Nelson, 1898 - C Chiapas, S Mexico.

D. t. moorei Warner & Harrell, 1957 - mountains of C Chiapas, S Mexico.

D. t. dolichonyx Warner & Harrell, 1957 - Sierra Madre de Chiapas, Chiapas, S Mexico.

D. t. sharpei Nelson, 1903 - SE Mexico (Campeche, Yucatán and Quintana Roo) and N Guatemala; possibly also Belize.

D. t. paynteri Warner & Harrell, 1955 - SC Quintana Roo, SE Mexico.

D. t. calophonus Warner & Harrell, 1957 - W Guatemala.

D. t. salvadoranus Dickey & van Rossem, 1928 - Volcán de San Miguel, El Salvador.

D. t. taylori van Rossem, 1932 - Mt Cacaguatique, El Salvador.

D. t. fuscus Conover, 1937 - Tegucigalpa Department, Honduras.

D. t. rufescens Warner & Harrell, 1957 - San Juancito Mts, Honduras.

D. t. conoveri - Warner & Harrell, 1957 - Olancho Department, Honduras.

Descriptive notes. 20-23 cm; male 180-266 g, female 168-206 g. Toes and claws very long. Overall coloration grey and brown with white streaks. Crown dark brown, collar buff with black spots; supercilium, chin, sides of neck and throat tawny orange; black streak extending from back of eye to collar. Back and wings mottled grey and brown, with white shaft streaks; rump olive brown or grey with black vermiculations. Breast and belly greyish brown with white streaks, lower belly white. Bill blackish brown, legs plumbeous. Female similar, but sides of head grey fading to white on throat; breast and flanks paler brown. Immature similar

but sides of head more cinnamon-buff in males and less ochraceous in females. Races separated on coloration and size: darker birds from montane forests, paler ones from more arid areas; largest individuals found in populations occurring in mountains, whereas smallest found near sea-level in Yucatán.

Habitat. Variable depending on population: subtropical montane and cloud forests at 1000-3000 m; in Yucatán Peninsula, locality to lower altitudes in deciduous scrub. Observed to be common in forests of oak and sweet gum. Found on forest floor with sparse understorey, and also in older second growth, especially at edges of old growth and clear-cut areas. Found in coffee plantations in El Salvador.

Food and Feeding. Small bulbs and seeds, e.g. pokeweed (*Phytolacca*), and insects including centipedes, crickets, fly larvae, grasshoppers and grubs. May eat coffee beans. Very strong feet and long claws allow food to be obtained by scratching in forest litter and soil.

Breeding. Season may extend from Feb to Oct: birds in breeding condition found during late Mar and Apr; in Yucatán, SE Mexico, nest found during May, and young chicks during Jul and Aug; young chicks in Tamaulipas, E Mexico during Apr; downy chick during Jul in Guatemala. Song distinctive and duetting reported. Clutch of 5 eggs found in Yucatán, where broods of 2-4. Eggs white with yellow markings, averaging 29-31 x 23.5-25 mm.

Movements. Presumably sedentary.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Very little information available; total population may number 100,000-500,000 birds. Appears to be locally common in many parts of range. Threats include deforestation, and possibly hunting and grazing in forests. Although found in small and rather isolated populations, apparently more capable of withstanding habitat destruction and fragmentation than other quails of Central and South America. Extensive surveys required.

Bibliography. Alderton (1992), Baepler (1962), Banks (1987), Binford (1989), Blake (1953, 1977), Davis (1972), Dickey & van Rossem (1938), Edwards (1989), Edwards & Lea (1955), Griscom (1932), Harrell (1951), Johnsgard (1973, 1988), Land (1970), LeFebvre & LeFebvre (1958), Leopold (1959), Monroe (1968), Paynter (1955), Ridgway & Friedmann (1946), Saunders *et al.* (1950), Schaldach (1963), Schönwetter (1967), Smithe (1966), Sutton & Pettingill (1942), Warner & Harrell (1957).

Genus *CYRTONYX* Gould, 1844

30. Montezuma Quail

Cyrtonyx montezumae

French: Colin arlequin **German:** Montezumawachtel **Spanish:** Colín de Montezuma
Other common names: Harlequin Quail; Mearns Quail (*mearnsi*); Salle's Quail (*sallei*)

Taxonomy. *Oryx Montezumae* Vigors, 1830, Mexico.

May be conspecific with *C. ocellatus*, with which forms superspecies. Race *sallei* sometimes considered full species. Five subspecies recognized.

Subspecies and Distribution.

C. m. mearnsi Nelson, 1900 - scattered populations in S USA (W & C Texas, S New Mexico and S Arizona) and N & NW Mexico. Also reported from Nayarit, CW Mexico.

C. m. montezumae (Vigors, 1830) - Tamaulipas S through Hidalgo to Oaxaca, E Mexico; sometimes claimed not to occur in Oaxaca.

C. m. merriami Nelson, 1897 - Mt Orizaba, Veracruz, EC Mexico.

C. m. sallei J. Verreaux, 1859 - S Michoacán, Guerrero and W Oaxaca, S Mexico.

C. m. rowleyi Phillips, 1966 - Guerrero and Oaxaca (Sierra de Miahuatlán), Mexico.

Descriptive notes. 20-22 cm; average in Mexico, male 195 g and female 176 g, but in Arizona, USA, male 209 g and female 193 g. Very distinctive head pattern; heavy spotting on flanks distinguishes from *C. ocellatus*. Crest tan, head mostly blackish, with forecrown stripe, orbital and postorbital areas, sides of neck and part of throat white; throat black medially, as is malar region. Overall coloration greyish to olive brown, combined with black and white. Hind neck and back olive brown with buff streaks; rump greyish, with white feather shafts, and brown and black barring; scapulars and upperwing-coverts olive brown, with black barring

and tan streaks. Sides of breast and belly black with large white, cinnamon or rufous brown dots; breast medially brown, turning to black on belly. Bill bluish grey, legs grey. Female has crown and small crest buffy with black spots; sides of head white with tan streaks, throat white; back, rump and wings olive brown, with buff shaft streaks and black spots; breast and belly tan with black streaks, medially fading to white or buff streaks on side. Immature resembles female, but young males acquire black belly. Races separated on coloration; *merriami* lacks white band behind black throat; *mearnsi* has upperwing greyish; *sallei* intermediate between nominate *montezumae* and *C. ocellatus*.

Habitat. Open pine and oak woodlands, pure oak woodlands and oak grasslands at 1060-3000 m. Found on forest floor and in thick brush.

Food and Feeding. Primarily bulbs and tubers during dry periods, and insects during wet season. In Mexico, bulbs of *Cyperus esculentus* most common, but also bulbs of *Oxalis*, *Brodiaea* and *Echeandia terniflora*; also seeds and fruits of legumes, wheat, corn, *Physalis*, *Kalmia latifolia*, *Arbutus*, *Juniperus*, *Pinus cembroides*, *Rhus*, *Quercus virginiana* and *Helianthus*. Animal foods include Hymenoptera, Diptera, Lepidoptera, Coleoptera, Homoptera, Orthoptera, Isoptera, Araneida, and Chilopoda. Similar in Arizona, USA, with *Oxalis* and *Cyperus* most important items. Most noted for stout legs and long claws for digging up tubers and bulbs. Standing water apparently not needed.

Breeding. In Arizona, pairing Mar-May and nesting late Jun-Sept, apparently coinciding with summer rain. Domed nests constructed with lining of grasses or oak (*Quercus*) leaves, and roofed with grasses; 15 cm diameter and 10 cm high. Average clutch 11-1 eggs (6-14); eggs white, although often stained, averaging 32 x 25 mm. Incubation 25-26 days; males reported incubating eggs and assisting with rearing of brood.

Movements. Sedentary. Occurs in coveys of 7-8 birds, rarely up to 25. Home range of up to 50 ha, but usually under 6 ha.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Total population may number over 500,000 birds. Populations and range in USA declining, as result of overgrazing; but overall population in USA stable since 1960's. Possible threats include deforestation and hunting. In Mexico, overgrazing possibly detrimental; in Arizona, USA, grazing of over 55% of vegetation can eliminate a population; in Texas, USA, grazing of 40-50% of tall grasses results in extirpation. Better studied in USA than in Mexico. Race *sallei* (sometimes considered full species) currently considered near-threatened. Races *mearnsi* and *montezumae* on CITES II.

31. Ocellated Quail

Cyrtonyx ocellatus

French: Colin ocellé

German: Tränenwachtel

Spanish: Colín Ocellado

Taxonomy. *Oryx ocellatus* Gould, 1837, unknown = Guatemala.

May be conspecific with *C. montezumae*, with which forms superspecies. Possible race *differens* described from Honduras, but not usually considered valid. Monotypic.

Distribution. S Mexico, through W Guatemala, E El Salvador and Honduras to N Nicaragua.

Descriptive notes. 19-23 cm; estimated weight of male 218 g, of female 182 g. Very distinctive head pattern; unlike *C. montezumae*, spotting on sides of upper breast fades away on flanks; breast and sides cinnamon, with grey tips on sides. Crown and hindneck olive brown; sides of head and neck bluish grey; orbital and post-orbital areas, side of neck and part of throat white; throat medially black, as is malar region. Overall coloration grey, brown and cinnamon. Back, rump, scapulars and upperwing-coverts grey and brown with cinnamon streaks and black spots, fading to chestnut streaks and black spots towards rear; primaries with white spots; belly black. Bill black to pale blue, legs grey. Female has brown crown with black spots; less extensive white on head, with black feather tips; malar region and side of head tawny, with black streaks rather than bluish grey; back, rump, scapulars and upperwing-coverts brown, with black vermiculations and buff stripes; breast and belly vinaceous, with black streaks along feather shafts. Immature most like female, but young males have more white on throat and some black on belly.

Habitat. Open pine and oak woodlands and brushy fields at 750-3050 m. Found on forest floor and in thick brush.

Food and Feeding. Most likely similar to *C. montezumae*, especially in use of *Oxalis*.

Breeding. Nesting season possibly Apr-Aug in Guatemala. Egg size 32.3 x 25.1 mm.

Movements. Apparently sedentary. Coveys of about a dozen birds reported.

Status and Conservation. Not globally threatened. Mace-Lande: possibly Safe. Currently considered near-threatened. Total population may number under 50,000 birds, and declining. Restricted range; very little information available. Said to be rare in S Mexico in early 1970's, perhaps as result of habitat deterioration due to overgrazing. Current threats may include deforestation, hunting and overgrazing. In S Mexico, birds of this species often kept as pets in cages. Surveys required.

Bibliography. Alderton (1992), Alvarez del Toro (1952), Binford (1989), Blake (1953, 1977), Briggs (1954), Davis (1972), Dickerman (1987b), Dickey & van Rossem (1938), Edwards (1989), Edwards & Lea (1955), Griscom (1932), Johnsgard (1973, 1988), Land (1970), Leopold (1959), Monroe (1968), Ridgway & Friedmann (1946), Saunders *et al.* (1950), Thurber *et al.* (1987).

Genus *RHYNCHORTYX* Ogilvie-Grant, 1893

32. Tawny-faced Quail

Rhynchortyx cinctus

French: Colin ceinturé

German: Langbeinwachtel

Spanish: Colín Carirufu

Other common names: Banded Wood-quail

Taxonomy. *Odontophorus cinctus* Salvin, 1876, Veraguas, Panama.

Birds of E Panama have been separated into race *hypopius*, but this division not normally accepted.

Three subspecies recognized.

Subspecies and Distribution.

R. c. pudibundus Peters, 1929 - NE Honduras and E Nicaragua.

R. c. cinctus (Salvin, 1876) - Caribbean coast of Costa Rica and Panama.

R. c. australis Chapman, 1915 - Pacific coast of Colombia & Ecuador.

Descriptive notes. 17-20 cm; male 165 g. Forehead, sides of head, and malar region rufous; black streak through eye to side of neck. Overall coloration grey and brown. Crown and hindneck dark brown; neck and upper breast grey; back and rump fading from grey to brown with black streaks; scapulars and coverts mottled with black and cinnamon, and white shaft streaks; lower breast and belly tawny buff, fading to white between legs. Bill and legs bluish grey. Female generally browner, with dark brown crown, head and neck; white eyeline, chin and throat; white streaks on side of head; back and upper breast brown, rump mottled

brown and chestnut, with small white spots; scapulars and upperwing-coverts olive and brown, with large black spots, small white spots, and white feather shafts; lower breast and belly with black barring along front and sides. Immature male resembles female but darker and less brown above. Races differ in plumage tone, *pudibundus* generally paler, *australis* darker.

Habitat. Lowland tropical forest at elevations under 1410 m. Most commonly found on forest floor.

Food and Feeding. Seeds, worms and insects recorded. Tends to peck with bill rather than scratch in litter.

Breeding. Female with developed egg collected during Mar, and downy young during Mar and Apr in Panama. Eggs white, measuring 29.6-30.4 x 23.5-23.8 mm.

Movements. Presumably sedentary. Usually found in pairs, but groups of up to 8 birds reported.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Very little information available; total population may number under 500,000 birds, perhaps declining. Apparently common in parts of Colombia, but rare and local in other areas. Rare and local in Panama, and no definite reports in W Panama. Major threats possibly include deforestation and hunting. Extensive surveys required.

Class AVES
Order GALLIFORMES
Suborder PHASIANI
Family PHASIANIDAE
(PHEASANTS AND PARTRIDGES)

- Small to large terrestrial birds, with plump body, short, stout bill, short, rounded wings and short or very long tail; plumage drab or spectacular.
- 14-250 cm (maximum includes tail 160 cm).

- Old World, with greatest diversity in SE Asia and Africa.
- Open areas or forest, from sea-level up to snow-line.
- 38 genera, 155 species, 399 taxa.
- 40 species threatened; 1, probably 2, species extinct since 1600.

Systematics

Phasianidae is the largest family in Galliformes, comprising some 155 species distributed throughout much of the Old World. The Galliformes are generally thought to be most closely related to the Anseriformes, perhaps linked by the screamers (Anhimidae). However, although many authors support this view, it has also been claimed that the two orders are not closely related, because the Anseriformes are derived from Charadriiformes.

Whilst there is a large fossil record for the Galliformes, a revision of all available material is urgently needed before much can be said about the evolutionary history of the order. There seem to have been many different pheasant- and partridge-like species present in Europe during the Tertiary, the earliest fossils appearing to be those in Britain which were deposited during the Lower Eocene. All those that date to before the Pliocene are considered to belong to genera which are now extinct, although a mid-Miocene fossil found in Namibia may prove to be that of a primitive francolin.

Within the Galliformes, the composition and relationship of the families has provoked as much discussion as the relationships of the Galliformes with other avian orders. The relationships between the families have been the subject of much study, the features investigated including osteological characters, wing muscle anatomy, DNA-DNA hybridization, immunology and karyology. There have been various proposals of different arrangements into suborders and superfamilies. The Hoatzin (*Opisthocomus hoazin*) has often been considered a galliform, although it has tended to be split off from all the remaining 280 or so species in its own suborder. In recent years there has been a move to transfer it to the Cuculiformes, but as there are strong opponents to both this version and the more traditional one, and as there is no decisive evidence to link this species closely with either group, it is probably best treated in its own monospecific order.

Once the Hoatzin is excluded, most authors have tended to arrange the remaining species into two or three discrete groups, usually separating the megapodes and cracids from all the other species. Current feeling is mostly that the order should be split into two suborders, but there are three suggestions as to how the families might be partitioned between these two. It has been

proposed by some authors that one of the suborders should contain just the megapodes, by others that it should comprise the megapodes and the cracids, and by yet others that it should consist of the megapodes and cracids together with guineafowl. In each of these cases, the other suborder would be made up of the remaining families. The grouping together of the megapodes and cracids, on the one hand, and all other Galliformes, on the other, is the proposal that is most widely accepted, whereas a recent suggestion that the former be raised to order status, the Craciformes, is more controversial.

The family Phasianidae has itself, at times, been considered to include the turkeys, grouse, guineafowl and New World quails, in addition to the pheasants, partridges, Old World quails, snowcocks and francolins, essentially all the Gallifor-

Subdivision of the Phasianidae.

The discovery of the Udzungwa Forest-partridge was one of the major surprises for the ornithological world in recent years. It was first found in the Udzungwa Mountains of southern Tanzania in 1991, and was initially thought to be a francolin. When scientifically described in early 1994, it was placed in a monotypic genus, and is believed to be most closely related to the Arborophila hill-partridges of Asia. Its occurrence in Africa is therefore remarkable from a biogeographical perspective and may shed light on the evolution of the family.

mes except for the cracids and megapodes. The uncertainty of the phylogenetic relationships within this assemblage is attributable to the fact that, whilst external morphology and behaviour have diverged extensively among these species, the skeletal anatomy varies only subtly and relatively continuously. The result is that the assemblage typically comprises many genera, each containing few species, the phylogenetic relationships of which are unclear.

The reduction of the Phasianidae from this large collection of around 200 species to the 155 currently accepted is not universally agreed upon, and some recent classifications continue to include some or all of the guineafowl, turkeys, grouse and New World quails, as subfamilies within Phasianidae. What is apparent is that, with time, the various groups are increasingly being regarded as differing from each other in important ways. For example, the distant relationship that the New World quails have with the rest of this group has been appreciated for some time, but while their elevation to family rank was proposed a long time ago, it is only very recently that this view has been generally approved of. At the same time, the guineafowl, which are usually considered to link the Phasianidae with the Cracidae, have generally been restored to family status. The taxonomic status of both the turkeys and the grouse has continually alternated between family and subfamily, though again the family status of the grouse has recently been reasserted.

The differing opinions as to how the divisions may best reflect phylogenetic affinities are again evident below the family level, within the Phasianidae. Whilst the use of two subfamilies, the Phasianinae and Perdicinae, is useful, the relationship is by no means so clear cut. When considering the expanded Phasianidae referred to above, for example, some six subfamilies were proposed, three of which included species covered herein: Pavoninae, comprising the two Asiatic peafowl, the argus pheasants, the peacock-pheasants and the Congo Peafowl (*Afropavo congensis*); the Gallinae, which included the junglefowl, the Old World quails, the partridges and the francolins; and the Phasianinae, made up of the "true" pheasants and the New World quails, which are now separated in the Odontophoridae. The tragopans and the Blood Pheasant (*Ithaginis cruentus*), usually placed alongside the true pheasants, have

often been thought of as the link between the partridges and the pheasants, because of their partridge-like behaviour.

Furthermore, a recent study of 12 galliform species using multilocus protein electrophoresis suggested that the peafowl are more closely related to the guineafowl than to other pheasants. A second finding was that the Grey Partridge (*Perdix perdix*) may, in fact, be a small pheasant rather than a partridge!

What is apparent from the large number of studies that have used many different techniques in attempts to unravel the relationships within the Galliformes in general, and the Phasianidae in particular, is that the relationships are still poorly understood. Indeed, at least 17 different phylogenies have been proposed. There are two separate requirements, however, which reflect different priorities. The first is that of understanding the affinities within the Galliformes, so that their evolutionary history and relationships can be explored. The second is the more immediate need for a standard list of species so that all those interested in the group who are not evolutionary biologists are clear that when one particular genus, species or whatever is being discussed, the different participants are all referring to a unit that is universally agreed upon. Ideally, the latter would be based upon the former, but given the many conflicting phylogenies proposed for the Galliformes, in practical terms this is far from easy. Fortunately, however, the standard list of species included within the Phasianidae has remained more or less consistent for most works. This is especially true of the pheasants, for which J. Delacour's sequence is usually followed.

In deciding on a suitable sequence for the pheasants, Delacour did not have an easy task. Much of the early pheasant taxonomy was based on the collection of one or a few specimens from few, often widely separated, localities. Subsequent reference to existing type specimens resulted in many taxa being proposed on the basis of minor differences. As an example, he faced a particular problem with what are nowadays known as the Kalij Pheasant (*Lophura leucomelanos*) and the Silver Pheasant (*Lophura nymthemera*), which have 9 and 15 subspecies respectively. These two species, long considered a superspecies, contain forms originally described as at least 49 different taxa in 28 species belonging to four genera.

The taxonomy of the many forms included in the Asian genus *Arborophila* is one of the main taxonomic problems affecting the Phasianidae. Some forms are treated as full species by some authors, but only as subspecies by others, while some are even considered by different authors to be subspecies of different species. Several have frequently been placed in a different genus, *Tropicoperdix*. This Common Hill-partridge shows some of the characteristic features of the genus, such as the striking black and whitish head markings and the small areas of bare red skin around the eye.

[*Arborophila torqueola*.

Hosking/FLPA]

Although much of the sequence of pheasants is largely undisputed, there are a couple of minor points of disagreement. One is the order of the two genera *Gallus* and *Lophura*, and the other is whether the Congo Peafowl should precede or follow *Pavo*. There are also a few cases of taxa which have alternatively been considered species or subspecies. The very little known Salvadori's Pheasant (*Lophura inornata*) of southern Sumatra differs only slightly in plumage markings from the north Sumatran form *hoogerwerfi*, which has, on occasion, been considered a full species, Hoogerwerf's Pheasant. However, the fact that the male Hoogerwerf's remains undescribed, and that the only two female specimens show very slight differences from female Salvadori's, have failed to convince most authors that Hoogerwerf's merits treatment as a distinct species.

The Vietnamese *Lophura* forms also pose a problem. Very few specimens are known from the wild, and these have been placed into two species, Edwards's Pheasant (*Lophura edwardsi*) and the Imperial Pheasant (*Lophura imperialis*). A third species was proposed from specimens collected in the 1960's. This form was named *Lophura hatinhensis* and has, regrettably, been thus treated as a full species in some quarters, although to date there is insufficient information upon which to accept this as a valid species. It is, at any rate for the time being, better placed within Edwards's Pheasant.

The original multitude of names for the Kalij and Silver Pheasants, the disagreement over the status of the Sumatran *Lophura* forms, and the differences between the few specimens of the genus collected in Vietnam indicate the considerable variation in the dark blue members of the genus and the Silver Pheasant, and at the same time they caution against the erection of new taxa without good evidence. By complete contrast the listing, sequence and composition of the congeneric firebacks and Bulwer's Pheasant (*Lophura bulweri*) are almost universally agreed upon.

Other instances of dispute at the specific level include that of the race *harmani* of the White Eared-pheasant (*Crossoptilon crossoptilon*), which is sometimes considered a full species, Harman's Eared-pheasant. A similar case is that of the Bornean Peacock-pheasant (*Polyplectron schleiermacheri*), which has traditionally been included within the Malaysian Peacock-pheasant (*Polyplectron malacense*); recent investigation

suggests that it is, in fact, a distinct species. Another area of uncertainty is the issue as to whether the Green Pheasant (*Phasianus versicolor*) of Japan is a valid species or a subspecies of the Ring-necked Pheasant (*Phasianus colchicus*). One final issue concerns the Great Argus (*Argusianus argus*) and its race *bipunctatus*, the Double-banded Argus. Whilst the single feather of the Double-banded Argus that resides in the British Museum is clearly from a bird that is closely related to the Great Argus, just how closely the two forms are related is not clear.

As with the Vietnamese *Lophura* forms, the first two of these issues, referring to the eared-pheasants and the peacock-pheasants, have implications for conservation priorities. After Edwards's Pheasant, the Bornean Peacock-pheasant is probably the most threatened pheasant in south-east Asia, and awarding it specific status does seem to present a clearer picture of the relationship between this form and the Malaysian Peacock-pheasant to the west, and the Palawan Peacock-pheasant (*Polyplectron emphanum*) to the east. Harman's Eared-pheasant, usually considered one of five subspecies of the White Eared-pheasant, is believed to be more at risk than any of the other races (see Status and Conservation). Understanding the relationships between all of these forms is important for species-orientated conservation initiatives.

The decision of which forms to include, and in what order, in the sequence of the *Perdiciinae* is far less clear, and this is a reflection of the greater uncertainty over relationships. This uncertainty has not led to so much controversy, presumably because most authors simply accept that the subfamily is poorly known and that much of the evidence appears to be conflicting. The main doubts seem to refer to relationships among the first few genera in the traditional sequence. The Snow Partridge (*Lerwa lerwa*) is always placed first, but the affinities of *Tetraophasis*, *Tetraogallus*, *Alectoris* and *Ammoperdix* are disputed, and there is generally rather limited agreement between the different authorities. Other issues include the position of the monotypic genera *Ophrysia* and *Anurophasis*, and whether *Francolinus*, *Coturnix* and *Arborophila* should each be split into two or more genera.

The genus *Francolinus* is the one striking exception to the generalization that Phasianidae contains small genera. As wide-

The Silver Pheasant is one of the pheasant species with the greatest geographical variation. In some races, the upperparts of the male are black, finely vermiculated with white, giving a very dark overall appearance. In others, however, they are basically white, with black markings of varying prominence. In the nominate race, these black marks are very narrow, so that white is the dominant colour on the upperparts, giving rise to the species' vernacular name. This male, photographed in Thailand, belongs to the race *jonesi*, which is approximately half way between these two extremes, as the black lines on the upperparts are fairly heavy. The overall appearance of some of the darker races is much more similar to that of some races of the Kalij Pheasant (*Lophura leucomelanos*), than to the whiter forms of the Silver Pheasant. These two species are normally considered to form a superspecies, but the taxonomy of both is far from clear. Some authors have suggested that the Silver Pheasant, with 15 races currently recognized, and the Kalij Pheasant, with nine, should be joined in a single species, as they replace one another geographically. Others propose the division of this complex into several species. The standard division into two species is based, above all, on the colour of the legs, crimson in all races of the Silver Pheasant and grey to brown in the Kalij, and also on the fact that in the former the males do not reach adult plumage until their second year, a year later than occurs in male Kalij Pheasants.

[*Lophura nycthemera jonesi*, Thailand.
Photo: R. Seitre/Bios]

The genus *Perdica*, comprising the four species of bush-quail, is restricted to the Indian Subcontinent. It is normally considered to be closely related to the typical *Coturnix* quails, due to their similarities in general morphological characteristics and in plumage pattern, particularly that on the upperparts. The wings, however, are more rounded, with the fifth, sixth and seventh primaries the longest, whereas those in *Coturnix* are somewhat more pointed, the eighth and ninth primaries being the longest. Within *Perdica*, the Jungle Bush-quail is the species with the strongest preference for stony substrates.

[*Perdica asiatica*.

Hosking/FLPA]

ly understood, this genus contains 41 species, although whether or not all these forms are best lumped in one genus is still unclear, despite a good deal of attention. Most attempts to interpret how the African and Asian francolins are related to each other have concluded that they are best placed within a single genus, *Francolinus*. Recently, however, T. M. Crowe and his colleagues have analysed 34 morphological and behavioural characters in all 41 species and in some other perdicines, and also restriction-fragment length polymorphisms of mitochondrial DNA of 13 African francolin species and one quail. The results suggest that the genus is composed of four major species assemblages: the five Asian species; two groups of African quail-like species; and the African partridge-like species. Consequently, it has been proposed that the genus be split into four genera, namely *Francolinus*, *Peliperdix*, *Scleroptila* and *Pternistis*. Whether or not this proposal will receive widespread acceptance remains to be seen.

The recommendations to alter the list of the francolins in the standard sequence of birds is based upon efforts to understand their phylogenetic affinities. In essence, Crowe and colleagues suggest that the francolins may not be a monophyletic assemblage as widely thought, for the analysis of morphological and behavioural characters show that the other perdicines included in the study bear more similarity to some francolins than do other francolin species. If, however, the monophyly of *Francolinus* is assumed, then there appear to be two major groups, those that are quail-like, and those that are partridge-like. Again assuming monophyly of the francolins, these workers go on to propose that the genus did not evolve in Asia, as previously supposed. Instead, they suggest that it evolved in Africa and that an early offshoot of the partridge-like francolins reached Asia and then diverged there. This divergence was estimated to have occurred during or before the middle to late Miocene.

The species which now seem to be generally accepted as the constituents of the genus *Coturnix* have, at times, been assigned to a total of three genera, *Coturnix*, *Synoicus* and *Excalfactoria*. In addition, seven, eight or nine species have variously been accepted for this genus.

Nevertheless, it is an understanding of the affinities of the assorted *Arborophila* hill-partridges that probably poses the greatest problems. That there are around 45 forms included in

this genus is not much disputed, but, as these tend to represent widely scattered populations, assessing the relationships between these populations is not easy. The taxonomic status of some forms has been varied by several authors, and the lack of wide acceptance of any one sequence is a clear indication of the need for a fresh approach.

Traditionally, the many forms have been split into 16, 17 or 18 species, comprising one or two genera. Several forms, typically the more northerly ones, are considered monotypic species, but further south there are several instances where the grouping of forms varies extensively, depending on the author. Monotypic species on which there is general agreement include the Collared Hill-partridge (*Arborophila gingica*), the Hainan Hill-partridge (*Arborophila ardens*) and the Orange-necked Hill-partridge (*Arborophila davidi*).

The differences of opinion on how best to treat the genus are greatest concerning the forms that have been alternatively assigned to the genus *Tropicoperdix* on some occasions. These ten forms inhabiting south-east Asian tropical forest do, however, share many morphological features with the other *Arborophila* forms, and are now more generally included within that genus, appearing to constitute one of four subgroups. Determining which of these ten forms are species and which are just subspecies is the most complex problem, and again there is no clear consensus. The most widely accepted version is that these ten forms comprise three species, the Green-legged Hill-partridge (*Arborophila chloropus*), the Annam Hill-partridge (*Arborophila merlini*) and the Chestnut-necklaced Hill-partridge (*Arborophila charltonii*).

Amongst the most exciting ornithological discoveries of the twentieth century have been two new species of Phasianidae, both of which have challenged evolutionary biologists. Both are African species, the Congo Peafowl, which was described for science in 1936, and the Udzungwa Forest-partridge (*Xenoperdix udzungwensis*), described in 1994. The occurrence of a pheasant in the Congo Basin caused considerable surprise to ornithologists, partly because it is such a large bird, but also because it may have Asiatic affinities. Subsequent taxonomic research has produced conflicting results, but it is usually considered more closely related to the peafowl, the two argus species and the peacock-pheasants than to the other pheasants.

Many pheasant species have facial decorations that play an important part in courtship displays.

Particularly striking are the face wattles of some members of the genus *Lophura*, covered as they are in small papillae and with a characteristic velvety aspect. Their colour and form differ from species to species and sometimes from race to race within any one species. In this Crested Fireback of the nominate race, *ignita*, the wattle has a large semi-circular lobe above the eye and a smaller lobe below pointing forwards. In contrast, the paler blue wattle of the race *rufa* has four lobes which are regularly spread around the eye.

[*Lophura ignita ignita*.

Bruce Coleman]

In July 1991, the Udzungwa Forest-partridge was first sighted in East African montane forest. Extensive investigation and comparison suggest that this "new" species is not closely related to other African species, but is a relict form, closest to the *Arborophila* hill-partridges of east Asia. Whilst study of the affinities of this partridge continues, the possible biogeographical implications of these two remarkable discoveries will certainly fuel discussions for years to come.

Morphological Aspects

Pheasants, partridges and their allies constitute a diverse family of small to large terrestrial birds which, nonetheless, share many morphological features. They are ground-dwellers, with squat bodies that are large in relation to the head, bill, short neck, wing and tail, although some pheasants do have long wings and tails. Some of these features are also common to other galliform families, such as the New World quails, but phasianids are generally less morphologically specialized than most of the other groups. For example, they differ from the cracids by lacking the morphological adaptations to living in trees, and they also lack the pectinated toes and feathered nostrils and tarsi of the grouse, the large feet of the megapodes, the mainly bare heads and bony helmets of the guineafowl, the breast adornments of the turkeys, and the serrations on the edge of the lower mandible of the New World quails.

Many of the scientific names of the phasianids do, however, refer to interesting morphological characters. This is especially the case among the pheasants. For example, the generic name of the monals, *Lophophorus*, comes from the Greek *lophos*, "crest", and *phorein*, "to bear", and that of the long-tailed pheasants, *Symnaticus*, is derived from the Latin *symmia*, a robe with a train, which refers to the long tail which is "dragged" behind the male.

There is considerable variation in size among phasianids. Species in the genus *Coturnix* are the smallest members of the family, weighing as little as 43 g, with a wing as small as 6.5 cm, as in the Asian Blue Quail (*Coturnix chinensis*). In contrast, male peafowl are amongst the largest flying birds, and, for example, the Indian Peafowl (*Pavo cristatus*) can weigh 6 kg

and have a wing as long as 50 cm. However, within these extremes most species weigh between 130 g and 2 kg, and have wing lengths of about 11–25 cm.

Males tend to be larger than females, although in some species the size ranges of the two sexes overlap considerably, and in *Coturnix* the females may average slightly larger than males. The stocky body has well developed breast muscles. As flight in most phasianids is restricted to short, strong bursts, large flight muscles are essential to enable the birds actually to become airborne, for short periods of rapid wing flapping.

The bill is usually short and robust, and it is well suited for digging in many species. The monals (*Lophophorus*), for example, have large bills and often dig the ground quite extensively when searching for tubers. The bill is not quite so substantial in some of the tropical forest species, which tend to scratch about among the leaf litter and turn over leaves with the bill, rather than digging in the ground.

The legs are strong, and often relatively short, adapted for the primarily terrestrial life that the species lead, which involves more walking and running than flying. Most species, including those that inhabit open country, prefer to move from place to place by walking, and even to escape by running, only taking to the wing as a last resort or when going to roost. For example, many open country francolins are considered difficult to flush, as they sit tight before suddenly bursting into the air or dashing off on foot.

One of the more conspicuous features of this family is the presence of spurs in the males, at least, of many species. The rear surface of the legs of many phasianids, guineafowl and turkeys often bears a spur, but these are absent from the other galliform families, Cracidae, Megapodiidae, Tetraonidae and Odontophoridae. The spur arises as a bony core towards the base of the hypotarsal ridge on the tarsometatarsus. In a number of species there is more than one spur per leg. For example, in Blyth's Tragopan (*Tragopan blythii*) it has been reported that a second spur can grow from the base of the first. It is more usual, however, for additional spurs to grow separately, emerging from the hypotarsal ridge between the original spur and the top of the tarsus.

The majority of males have one spur per leg, although some species often have considerably more. Male Malaysian Pea-

As its name indicates, the genus *Galloperdix* forms a sort of link between the two subfamilies of the Phasianidae: the partridges and their allies (including *Galloperdix*) of the *Perdicinae*; and the pheasants of the *Phasianinae*. Certain features visible in this male Red Spurfiowl are reminiscent of pheasants, such as the length and shape of the tail and the fairly large area of bare facial skin. Note also the tarsal spurs, which are particularly numerous in this genus, with up to three on each leg in males, and up to two per leg in females.

[*Galloperdix spadicea*.
Photo: Kenneth W. Fink]

cock-pheasants, for example, usually have two spurs per leg, but a total of seven has been recorded, three on one leg and four on the other. Indeed, the generic name *Polyplectron* is derived from the Greek, and means "many-spurred". Females, as well as males, of a few species possess spurs, such as all three spurfiowl (*Galloperdix*) of south Asia.

The function of the spurs has received surprisingly little attention. It seems not unreasonable to suppose that the spurs are primarily weapons used in combat between ground-dwelling males. However, it has recently been claimed, rather controversially, that the presence of these spurs has nothing to do with competition among males; instead, it is suggested that a female chooses her mate on the basis of the length of the spurs. The role that the spurs play in the life of those females that possess them is even more uncertain.

Among the pheasants in particular, the presence of a variety of facial adornments in the males is striking, whereas most of the partridges, quails, francolins and snowcocks lack such crests, wattles, ruffs and hackles. These specialized structures are used in courtship displays before females, and also, in some cases, during aggressive interactions with other males. Wattles and lappets are present in some members of *Tragopan* and *Lophura*, and are either not visible or much reduced when the male is not displaying. Facial wattles are most pronounced in the male Bulwer's Pheasant. Most of the time, the sky blue wattles almost cover each side of the face, and rise slightly above and hang just below the level of the head. When engorged during display, however, they can be extended down the neck to such a degree that they reach the back and also right down below the head, in the form of an arc, some 18 cm in length. All of the tragopans possess lappets, which are usually much reduced and inconspicuous. When the bird displays frontally, the lappet hangs down and is spread out, revealing bare skin that is often brightly patterned.

Crests, "horns" and ruffs, in contrast to wattles and lappets, are composed of feathers. Crests are found in a variety of species, of both partridges and pheasants, including the Crested Wood-partridge (*Kallulus rotundus*), the Kalij Pheasant and the peafowl. Horns are feathers which arise from each side of the head and are found in *Pucrasia* and *Tragopan*. The "ears" of *Crossoptilon* are similarly elongated feathers. Ruffs are found

only in the genus *Chrysolophus*, and these two species are commonly known as the ruffed pheasants. In some species, such as the Indian Peafowl, the crest is evident at all times, whereas in others, such as the Malaysian Peacock-pheasant, the crest is only erected during display. The ruffs of the male Golden Pheasant (*Chrysolophus pictus*) and Lady Amherst's Pheasant (*Chrysolophus amherstiae*) are fully expanded during display, when they form a semi-circle of feathers around and below the eye.

Many pheasant species have long been kept in captivity, because of the extravagant plumage patterns, usually of males, which have led to their being considered "ornamental". Among the partridges, quails, francolins and snowcocks, brightly coloured males are less common. As with the aforementioned wattles, crests and so on, the extravagant plumages have been assumed to play an important role in courtship, reflecting the reproductive pattern of the species concerned. Whilst some of the males are visually spectacular, the majority of females in this family can be described as cryptically patterned, in a combination of browns, greys, black and white. The result is a considerable degree of sexual dimorphism in some species, although this aspect varies quite remarkably across the family.

Two studies have investigated how the variation in the degree of sexual dimorphism throughout the whole order Galliformes might be correlated with various aspects of ecology and reproductive behaviour. H. Sigurjónsdóttir found that the greater the difference in size between males and females, the greater the difference in colour dimorphism as well. Generally speaking, males that are large and brightly coloured tend to help little in the raising of young, compared with those in the less dimorphic species. Sexual dimorphism was related to aspects of ecology and breeding behaviour by M. Ridley, who found that both size and colour dimorphism tended to be least pronounced in monogamous species. Forest inhabitants also seem to be both larger and more brightly coloured than those in open habitats, such as grassland.

Chicks are precocial, and vary in colour from pale sandy buff through to a range of browns, often with distinct dark markings, such as stripes, bars and patches. In many species, immatures resemble the adult female in patterning, but shading varies. Post-juvenile moult, at any rate in Western Palearctic

species, is complete, and, except in a few pheasants, males assume adult plumage in the first year.

The sequence of the moult of the tail feathers was proposed as a method of dividing the Phasianidae into four subfamilies, by W. Beebe in 1914. In essence, he found that there are four different sequences of tail moult in this family. Although he was not able to inspect all the genera, he suggested that, in the Old World partridges, quails, francolins and snowcocks, the Blood Pheasant and the tragopans, moult begins with the central rectrices and proceeds outwards. Conversely, in most of the pheasants, the sequence is from the outermost tail feathers inwards. In the argus pheasants (*Polyplectron*, *Argus*, *Rheinardia*), however, moult begins with the third feather on either side of the central pair and moves both inward and outward from this point. The fourth mode is that of the peafowl, in which the pair of feathers that are second from the outside are shed first and moult progresses inward, while the outermost pair fall just before the innermost ones.

The timing of moult in most Western Palearctic species is well known. All species undergo a complete post-breeding moult, the timing of which varies according to sex and locality. For example, the onset of moult in the Chukar (*Alectoris chukar*) is variable, depending upon when the breeding attempt is completed; females moult a little later than males. Transcasian populations of the See-see Partridge (*Ammoperdix griseogularis*) begin earlier than those further south in Iran and Afghanistan, but in most species in the region, moult is usually under way by May-July and completed by October-November. Much less is known about the timing of moult in wild populations of most other phasianids, but in the Great Argus of south-east Asia, moult appears to start between mid-May and the beginning of July, and may possibly last for 125 days; this approximation has been based on the finding of feathers on the forest floor.

Habitat

As most species in this family are fairly sedentary, or completely so, they use the same habitat throughout the year, and do not utilize separate areas for different activities, such as nesting, or feeding.

The two subfamilies in the Phasianidae show quite different patterns in their distribution and, therefore, habitat use. The pheasants, Phasianinae, are exclusively Asian in distribution, with the single exception of the Congo Peafowl. Several species have been introduced into Europe, North America and Australia, particularly the Ring-necked Pheasant, but also the Red Junglefowl (*Gallus gallus*), along with local introductions of a few species, such as the ruffed pheasants. Their natural distribution in Asia takes them from Java at 8° S, where the Green Peafowl (*Pavo muticus*) and Green Junglefowl (*Gallus varius*) occur, through the equatorial forests of Malaysia to Indochina and China, where the Koklass Pheasant (*Pucrasia macrolopha*), Reeves's Pheasant (*Symaticus reevesii*) and the Blue Eared-pheasant (*Crossoptilon auritum*) are amongst the most northerly species in the subfamily, at 50° N. Excluding the Congo Peafowl, the westernmost member of the subfamily is the Ring-necked Pheasant in the Caucasus, and pheasants occur along the Himalayas and eastwards to the Pacific Ocean, in Japan, where the Green Pheasant and the Copper Pheasant (*Symaticus soemmerringii*) can be found.

As with the pheasants, the distribution of the partridges, quails, francolins and snowcocks is centred on Asia, but it extends throughout much of the Old World. The south-eastern limit is found in Australia and Tasmania, given that the New Zealand Quail (*Coturnix novaezelandiae*) is now extinct (see Status and Conservation). Thence the group extends northwards through New Guinea, south-east Asia and China to nearly 60° N, where the Japanese Quail (*Coturnix japonica*) and the Tibetan Partridge (*Perdix hodgsoniae*) are found. Westwards, the group is distributed through south-east Asia, where *Arborophila* and several single-species genera occur, including the Crimson-headed Partridge (*Haematoryx sanguineiceps*), to the Indian Subcontinent.

Though basically ground-dwellers, many phasianids perch in trees or bushes when calling, especially in the early morning or late afternoon. This behaviour is more common among species that live in open habitats, such as the Grey Francolin. This species also has the habit, unusual for a francolin, of roosting in trees at night, and two birds will sometimes roost in close bodily contact. This species is very popular as a cage bird, partly due to its loud, ringing calls, which it makes throughout the year. In Pakistan, in the province of Sind alone, thousands of permits are granted every year to catch birds for this trade. Despite this pressure, it is still the commonest resident gamebird over most of its range, as a result of its high breeding potential and remarkable adaptability.

[*Francolinus pondicerianus interpositus*, Ranthambhor National Park, Rajasthan, India. Photo: Günter Ziesler]

The Snow Partridge's disruptive plumage pattern, mainly produced by the finely barred head, neck and upperparts, is highly cryptic, and provides very effective camouflage in its high altitude habitat which abounds in lichen-covered rocks. This is a monogamous species, in which pairs form a lasting bond, so in spring it is commonly found in pairs. Following breeding, however, flocks may form, with up to thirty birds coming together.

[*Lerwa lerwa*, Sagamatha National Park, Nepal.
Photo: Dieter & Mary Plagel]

which is home to the spurfowl (*Galloperdix*) and bush-quails (*Perdicula*) amongst others. Further west, the subfamily is represented in the Middle East by several genera including *Ammoperdix*. In Africa, most species in the large genus *Francolinus* are to be found, and in Europe *Perdix* and *Alectoris* occur. The group is absent from Saharan Africa, extreme northern Europe, northern Siberia and the Australian interior.

As might be predicted from the extensive area inhabited by the phasianids, the various species use a considerable

range of habitats. The pheasants mainly occur in forested or semi-forested habitats, ranging from ever-wet tropical forests to temperate scrub forest, although the Cheer Pheasant (*Catreus wallichii*) is an inhabitant of grassy hillsides with scattered crags.

Perdix gamebirds can be found in virtually every terrestrial ecotype, being absent only from tundra and boreal forest, where they are replaced by the Tetraonidae. They occur in both open country and closed habitats. Open habitats in which these species are found include a wide variety of tropical and temperate vegetation types, from deserts to montane pastures. Many species occur in tropical plains or savannas, for instance the Grey-breasted Francolin (*Francolinus rufopictus*) of East Africa, while temperate and steppe grasslands of Europe and northern Asia are home to the Grey Partridge amongst others. Philby's Partridge (*Alectoris philbyi*) of western Arabia is one of the relatively few species that occur in the desert, whereas high altitude alpine zones support several species, including the Tibetan Snowcock (*Tetraogallus tibetanus*) of the Pamir and Himalayan Ranges. At the other extreme, perdixines are found in forested habitats, such as the lowland tropical rain forests used for example by the Crested Wood-partridge of south-east Asia and Latham's Francolin (*Francolinus lathamii*) of Africa. The Red-billed Hill-partridge (*Arborophila rubrirostris*) of Sumatra inhabits montane tropical forest, and subtropical forests are also home to several species, including the Sichuan Hill-partridge (*Arborophila rufipectus*) in south-western China.

Phasianid habitats are distributed from the lowlands up to high alpine meadows in both temperate and tropical areas. The family occupies mountain slopes throughout its range, such as the Caucasus, where the Caucasian Snowcock (*Tetraogallus caucasicus*) can be found; Mount Elgon and the Aberdares in East Africa, which are home to Jackson's Francolin (*Francolinus jacksoni*) and the Moorland Francolin (*Francolinus psilolaemus*); and the Himalayas in Asia where several species occur, including the Koklass Pheasant and the Chestnut-breasted Hill-partridge (*Arborophila mandellii*). In the Himalayas and western China, pheasants and partridges can be found above 4000 m in the summer and the Chinese Monal (*Lophophorus thuyii*) may not even descend much lower dur-

In common with the tendency in many other bird groups, those partridges that inhabit the interior of tropical forests generally have brighter plumage than those of more open habitats. A case in point is the Ferruginous Wood-partridge of the Malay Peninsula, Sumatra and Borneo, with its bright rusty brown head and breast, its black and white mantle and the ocellus-like black spots on its wings.

[*Caloperdix oculea*.

NHPA]

ing the winter. The snowcocks (*Tetraogallus*) are found up to the permanent snow-line which may be above 5000 m in some places.

Because not all habitats are equally widespread, the species which inhabit them have ranges that vary similarly in size. The relationship between habitat type occupied and the area of a species' range has been assessed for the francolins of Africa. There are many more francolins living in open areas in Africa than there are occupying forest and forest edge habitats; species of the latter habitat have ranges averaging about 100,000 km². For example, Nahan's Francolin (*Francolinus nahani*) is estimated to have a range of about 95,000 km², and the Handsome Francolin (*Francolinus nobilis*) of about 134,000 km². The non-forest species, however, commonly occupy areas greater than this, and many cover 1,000,000 km² or more, such as the Coqui Francolin (*Francolinus coqui*), which is distributed over more than 4,000,000 km², and Swainson's Francolin (*Francolinus swainsonii*) which covers about 1,500,000 km². This relationship has not been studied critically throughout the whole family, but it does appear to apply broadly. Many species of both pheasant and partridge inhabiting south-east Asian rain forest, for example, have distributions of less than 100,000 km². In contrast, most of those living in the grasslands, plains and semi-arid ecosystems of the Palearctic and Africa have ranges greater than this, and many are considerably larger than 500,000 km².

Species which occupy climax habitats, such as mature forests, are typically restricted to these areas, whereas some of those that occur in non-forested habitats live in a range of vegetation types. For example, the Double-spurred Francolin (*Francolinus bicalcaratus*) is found in a wide range of open habitats in Africa, from moist savanna to arid savanna, and including a variety of forms of cultivation and moist Mediterranean vegetation near the coast. Similarly, Swainson's Francolin, while preferring dense grassland, also lives in thornbush with sparse cover, bushveld and along the edges of woodland.

At a fairly general level, the type of vegetation that each species uses is well known in most cases. As more studies are conducted at a finer scale, that of the micro-habitat, however, it is becoming apparent that some phasianids show very par-

ticular patterns of habitat use. Once a species has been recorded in a certain habitat type, it has been common practice to assume that it occurs throughout the range of that particular vegetation type. But now this convention is being revised in several cases. For example, it is now known that Malaysian Peacock-pheasants do not use all parts of the primary lowland forest in which the species is found in Peninsular Malaysia; it uses areas by slow meandering rivers and those that are less disturbed by tree-falls. It also appears to have particular requirements when it comes to making display scrapes, choosing parts of the forest near seasonal inland swamps. Consequently, the area really inhabited by the species is probably much smaller than originally thought, as it may be patchily distributed throughout the lowland forest.

Similar studies have shown that the Cheer Pheasant is restricted to grassland in early stages of succession on mid-altitude slopes of the western Himalaya, and that during the winter Cabot's Tragopan (*Tragopan caboti*) preferably uses the patches of forest that contain more of the nut-bearing tree *Daphniphyllum macropodum*. The patterns of habitat use of the Ring-necked Pheasant in its introduced range probably constitute one of the most intensively studied subjects in the family. In the managed woodlands of southern England, female density is highest where there are more shrubs, whereas male density is highest where there are more food hoppers, and also in the woodlands with the greatest length of edge. In spring, both sexes are found close to the woodland edge, feeding in fields on the one side and nesting in the woodlands on the other, although later on in the breeding season, females nest in tall cereal crops as well.

General Habits

There is considerable variation in the group size in which phasianids occur, both throughout the family and within some species between seasons. Individuals of both sexes in some species are believed to remain solitary throughout the year. Several pheasants in south-east Asia are not known to associate with conspecifics for any length of time at all, the two sexes meeting only to copulate, as in the Great Argus and the Crested

Of the many ornamental features which make male pheasants so spectacular, one of the most notable is the extraordinary growth of certain feathers in some species. The male Great Argus, for example, has remarkably long central tail feathers, four times the size of the outer feathers, and extremely long, broad secondaries, which far exceed the primaries in length. In addition, each secondary is decorated with a chain of up to 20 large golden ocelli, which are most effectively displayed during the astonishing courtship dance. In normal circumstances the ocelli remain concealed, however, making the plumage appear much duller, and even cryptic against the background of the forest floor.

[*Argusianus argus argus*.

Hosking/FLPA]

Argus (*Rheinardia ocellata*). In contrast, many open country species are often found in larger groups, at least outside the breeding season, and often in pairs whilst breeding. Some of the African francolins, such as the Grey-winged Francolin (*Francolinus africanus*) of South Africa, form groups of up to 15-20. There are also reports of eared-pheasants (*Crossoptilon*) in China occurring in flocks of up to 100 birds during the winter.

It has been suggested that group size in phasianids is a compromise between protection from predators and conspecific males, on the one hand, and access to mates, on the other. In this proposal, males guard the females from predators and the unwanted attention of many other males of the same species, in return for exclusive mating opportunities. This is particularly important in open habitats, where there is less concealing vegetation and the male-female bond is prolonged, either in a pair, as in the Swamp Francolin (*Francolinus gularis*), or in a harem, if the females are gregarious during the breeding season, as is the case in the Ring-necked Pheasant. In closed forest habitats, where females can be concealed by vegetation, males do not need to guard them, and as a result many more species are solitary, for instance the Palawan Peacock-pheasant. There are exceptions to this generalized scheme, such as the Crested Fireback (*Lophura ignita*), an inhabitant of primary rain forest, which can be seen in flocks of up to ten individuals.

As already suggested, the degree to which some species are gregarious varies through the year. Whilst during the non-breeding season a number of phasianids are to be found in groups, these tend to disperse during the breeding season. For example, the Double-spurred Francolin occurs in groups of up to 12, or even 40, individuals, but is found almost invariably in pairs immediately before and during the breeding season. Also, in the monogamous Cheer Pheasant, it is reported that several pairs will join together to form a single flock during the winter.

The daily routine of phasianids generally follows a simple pattern. After emerging from the roost, birds feed, before retiring to shelter during the middle of the day, reappearing to feed in the late afternoon. Many open country species, for example the Chukar, feed in open areas in the early morning, before retreating to patches of scrub, to dense areas of long grass or under rocky ledges; late afternoon foraging in this species is often conducted near water. The daily activities of forest phasianids are very little known. Radio-tracking of a few Malaysian Peacock-pheasants revealed that birds were mobile for much of the day: there was no predictable midday resting period. Conversely, the male Great Argus was found to spend some time sitting on low branches near dancing grounds during the day. For at least part of the year many phasianids, primarily the males, start the day by calling. In open country this calling is often from atop rocky outcrops or perches in trees or bushes. Some forest species, such as the Malaysian Peacock-pheasant and the Satyr Tragopan (*Tragopan satyra*), are known to call from elevated branches 10-20 m off the ground.

Whilst the way in which phasianids spend their day in some habitats and situations is broadly known, detailed daily activity patterns are understood in only a few species. In southern England, the time budget of feral Red Junglefowl differs between the sexes during spring. Both sexes sit, stand, are vigilant, walk, preen, search for food whilst walking, scratch and peck at food, and engage in interactions. While males spend more of their time (37%) standing than in any other activity, females spend only 12% of their time simply standing. Nearly half of the females' time (47%) is spent feeding by scratching and pecking at food, whereas this activity accounts for only 14% of the males' time. When the females are with young, they also brood the chicks and spend nearly 60% of their time scratching and pecking at food.

Imprinting and social dominance are two aspects of behaviour that have been well studied in this family, or more specifically in domestic fowl. These traits are well developed in phasianids because of their lifestyle, in which imprinting and the establishment of peck orders play important roles. Filial imprinting begins virtually at hatching, and, under natural con-

In the cock Lady Amherst's Pheasant, the tail feathers are remarkably long, measuring at least 100 cm, and sometimes more than twice the length of the head and body. This species is also a good example of the richly varied colouring of some cock pheasants' plumage. Various shades of red, orange, yellow, green, blue, brown, grey, black and white are all present in this marvellous bird. The large ruff of rounded feathers starting from the nape is spread like a fan around the head and neck during courtship display, when the small wattle under the eye, clearly visible in this bird, is expanded into a lappet covering the lower part of the cheek. The species was described in 1829 from two cocks sent to London by Lord Amherst, both of which died shortly after arrival. Later imports of birds, from 1869 onwards, rapidly led to the species being well established in captivity in Europe, and, as a consequence of its beauty and the ease with which it is kept and bred, it soon became a favourite with aviculturalists.

[*Chrysolophus amherstiae*. Photo: Kenneth W. Fink]

All pheasants, as well as the vast majority of the other members of the family, are very poorly adapted for long sustained flight. They do, however, have powerful pectoral muscles, which allow them to take off rapidly and thus escape danger, at times when running away is not sufficient. The longest recorded non-stop flight by a Ring-necked Pheasant was of 6.5 km, in order to cross water. This is exceptional, however, as many birds have fallen, exhausted, into water when trying to perform much shorter crossings.

[*Phasianus colchicus*.

ditions, ensures that the precocial chicks follow the parent rather than other moving objects, such as another bird species or mammal. In the *Coturnix* quails, sexual imprinting, the process of learning the characteristics of the species, is highly specific, and individuals prefer mates that are similar, but not identical, to their immediate family. This results in mating with distant relatives rather than siblings or unrelated birds.

In social phasianids, the peck order, or dominance hierarchy, within a group is considered a mechanism for social integration. Both Red Junglefowl and Ring-necked Pheasants have linear hierarchies, and there is anecdotal information that suggests that dominance patterns occur in other pheasants and partridges. For example, it appears that dominant male Double-spurred Francolins lead groups, exceptionally of up to 40 birds, as they wander through open vegetation.

Voice

The crow of the domestic or village cock is one of the most familiar natural noises the world over. What may not be such common knowledge is the fact that the Red Junglefowl, most likely the wild ancestor of the domestic chicken, has an extensive vocal repertoire, which is rather well known compared with those of other phasianids, and indeed of most other birds. Many other pheasants, partridges, quails, francolins and snowcocks also have very conspicuous calls, and in some cases their calls are particularly evocative of the areas within which they live. For example, the far-carrying wailing cry of the Great Argus is one of the most distinctive sounds of the rain forest covered hills in the lowlands of Malaysia and Indonesia, and likewise the harsh call of the Koklass Pheasant is typical of dawn on cool spring mornings in the mid-altitude forests of the western Himalayas.

Pheasants, partridges and their allies have a wide range of calls, with which they communicate in a great variety of situ-

ations. Advertising calls, contact calls, alarm calls and contentment calls are among the vocalizations described for these birds. They range from sounds audible to the human ear only at a few paces, to others, such as that of the male Crested Argus in the breeding season, that can be heard for several kilometres. Some calls are given throughout the year and others only during the breeding season, depending upon the species, context and function.

Fairly complete repertoires have been described for several species. In addition to the case of the Red Junglefowl, the calls of the Grey Partridge, the *Alectoris* partridges, the Cheer, the Kalij and Lady Amherst's Pheasants, the Malaysian Peacock-pheasant and the Great Argus, among others, have been quite fully described. Only in a few species, however, has the function of the calls been adequately explored.

There is considerable variation in group size among phasianids both according to species, and in some cases time of year or habitat (see General Habits). As calling is a major channel of communication between individuals, it is no surprise that the vocal behaviour of the phasianids reflects this diversity of social patterns. So, on the one hand there are species which are believed solitary and for which few different calls are known, such as the Great Argus, and on the other extensive vocal repertoires are reported for some gregarious species, most notably the Red Junglefowl. It should be stressed, however, that knowledge of sounds made by phasianids still remains very patchy. The calls of most northern temperate species have been documented, and, in many cases, their function implied or demonstrated experimentally, whereas knowledge of most other species is restricted, at best, to descriptions of some of the louder calls. Therefore, any account inevitably relies on well studied cases for examples; these should not be taken as exhaustive lists.

In the largely solitary species it appears that vocal communication is mostly used by males during the breeding season, when they give loud advertising calls and also emit quiet noises

As one would expect for such eminently terrestrial birds, phasianids have strong legs that are well adapted for walking and sometimes running, often over broken terrain. The bushy reddish occipital crest, the glossy bluish black plumage, the bright red base of the bill and bare skin around and behind the eye, make the male Crested Wood-partridge one of the most striking of all the *Perdicinae*. This species, an inhabitant of the tropical forests of south-east Asia, shows notable sexual dimorphism; unusually, the plumage of the female is not cryptic, but instead is predominantly bright grass green.

[*Rollulus rouloul*.

during close contact, which may be in courtship display to females or in aggressive encounters with other males. Females of these solitary species appear to be far less vocal, and why they should, occasionally, make loud calls is not at all clear. Gregarious species, whether they form winter flocks of birds of breeding age, or are family coveys remaining together until the young reach their first breeding season, have much larger repertoires. This reflects the greater social contact that individuals have and the variety of contexts in which communication is required, such as for keeping the flock together, alerting others to the proximity of potential predators and reassembling when the group is split.

The calls themselves vary considerably in structural features, such as frequency, duration and amplitude, and it is worth briefly describing some of these vocalizations with reference to their contexts and functions.

Many of the calls given by species which flock are quiet noises, important only within the group context. Hence they only need to be audible over a few metres so that other flock members can hear; good examples are the contentment notes emitted by the Red Junglefowl and the contact calls of Grey Partridges. These are probably different names for calls which serve a similar, if not identical, function. Both have harmonically complex structures, at least in part, and are primarily of low frequency. The contact call of the Grey Partridge comprises two types of note, two short, wide frequency notes given far apart, followed by a short series of narrower frequency notes emitted rapidly. The contentment call of the Red Junglefowl, in contrast, is a simple series of similar calls. In both species, the calls are uttered by both sexes and can be heard during activities such as feeding, cleaning, sand-bathing and resting, and they seem to function as group cohesion or social contact calls. Feeding flocks of Caspian Snowcocks (*Tetrao gallus caspius*) also call continually to one another. Most of the species which form coveys are known to give contact calls, including the See-see Partridge, the Còqui Francolin, the Scaly Francolin (*Francolinus squamatus*), Hartlaub's Francolin (*Francolinus hartlaubi*), the Crested Wood-partridge and the Blood Pheasant.

If individuals in a covey have been separated, they typically re-establish contact with rally calls. In the Grey Partridge these

are given by both sexes at all ages. Individuals emit the call alternately, when standing upright and with the neck outstretched. The call is of higher frequency than the contact call in this species, most of the sound being between 3.2 and 4.8 KHz. Structurally, each note usually comprises three elements, although the second can barely be detected or is even absent in some cases. After being dispersed, Blood Pheasants give loud, shrill calls of three to seven notes, which serve to bring members of the covey back together. It is possible that whilst birds are attracted to calls from others in their covey, they are repelled when the rally call is given by individuals from other coveys. Other species in which covey re-formation in this way has been documented include the *Alectoris* partridges, the Crested Wood-partridge and the Jungle Bush-quail (*Perdica asiatica*).

In some species, the contact and rally calls serve to maintain and re-establish contact between parents and chicks, as well as among adults. In these species, and those which are largely solitary, there are also vocalizations that are used only when parents are with their offspring. These may be termed "family calls", and include several utterances given in different circumstances. Grey Partridge parents, for example, hiss when a potential predator appears, one parent gathering the young together, and the other approaching the intruder aggressively, hissing all the while. Female Rock Partridges (*Alectoris graeca*) repeatedly utter monosyllables when feeding with chicks, and these notes escalate into phrases when the females try to draw their chicks to new food sources.

Communication between adults and young begins even before the eggs hatch. A study of Ring-necked Pheasants showed that chicks exposed to vocalizations made by an incubating female during the last week of incubation differed in their behaviour, during the first week after hatching, from those chicks incubated in silence during the last week. Responses to feeding and caution calls made by the adult female were stronger in those chicks that were exposed to incubation calls than those incubated in silence. An interpretation of this is that the calls of the incubating female serve to make chicks familiar with these important calls immediately upon hatching, thus enabling them to act appropriately at an extremely early stage. Synchronous hatching may also be promoted by

Areas of rich grass cover, such as open grassland and savanna, are the preferred habitat of Shelley's Francolin. Unlike the phasianids that inhabit mature forests, and are normally tightly restricted to them, those species that live in open areas generally use a wider range of habitats. Shelley's Francolin can also be found in thornveld, clearings in woodland, stony or rocky terrain and locally even cultivation. It can be found from coastal areas to mountains, up to at least 3000 m.

communication between chicks during the latter stages of incubation.

Other vocalizations used between adults in groups include dominance and submissive calls, such as the peeps and squeals of the male *Alectoris* partridges, and low frequency, harsh threat calls issued by dominant Red Junglefowl to submissive individuals. Chicks also emit contentment notes when they are untroubled, as reported in *Alectoris* partridges, the Ring-necked Pheasant and the Common Quail (*Coturnix coturnix*).

Alarm calls are typically loud and harsh-sounding to the human ear. These include those that are given when individuals in forested habitats are disturbed by an intruder some distance away, as occurs in the Palawan Peacock-pheasant, and also those uttered when a bird "explodes" into the air in more open country, as is typical of the Grey Francolin (*Francolinus pondicerianus*). Calls which have been interpreted as alarm calls are given by both solitary and gregarious species. The Malaysian Peacock-pheasant, essentially a solitary inhabitant of primary lowland rain forest in south-east Asia, at some times of the year gives alarm calls whilst still some distance from an intruder. These calls are explosive noises of wide, and essentially low, frequency; each call may constitute many notes and can be repeated many times. In contrast, some other gallinaeous inhabitants of the same area are rarely heard at all. The gregarious *Alectoris* partridges and Lady Amherst's Pheasant are among those which have a variety of vocalizations that are used in distress situations. In *Alectoris*, these include: a ground alarm call, a shrill whistle which is uttered when flushed; a hawk alarm call, a short, guttural sound given when an aerial predator comes into view; and a loud, shrill scream that is given when a bird is attacked suddenly.

During the breeding season, males of many species use vocalizations that are heard only at this time of year and include advertising and courtship calls. It is the advertising calls that have tended to attract most attention, as they are typically loud and far-carrying, and are usually referred to as territorial, crowing and female attraction calls. In open country habitats, many males move to conspicuous positions to make these calls. Male Scaly Francolins, for example, use termite mounds and similarly exposed positions to call from,

and Himalayan Snowcocks (*Tetraogallus himalayensis*) often perch atop mounds, rocks, trees and bushes. The Double-spurred Francolin, which also inhabits non-forested areas, likewise gives its harsh, grating advertising call from prominent positions. The notes are principally of low frequency, with most energy emitted below 3 KHz, and notes repeated about every half second.

In the solitary, forest-dwelling Malaysian Peacock-pheasant and Great Argus, there appear to be two types of advertising call. In the former species, these "tchorrs" and whistles carry for up to 300 m through the forest undergrowth. The calls verbalized as "tchorrs" are harsh-sounding, and each call contains a single note of narrow frequency range, usually below about 2 KHz, and lasting between half a second and a full second. Whistles are a melancholy double note call, the second note of higher frequency than the first. They are also of narrow frequency range, although, at less than 1.2 KHz, they are lower-pitched than the "tchorrs". Both calls are often repeated many times, and both are sometimes heard in the same bout, in which case "tchorrs" are always emitted first. It has been suggested, from observation, that the number and type of calls given by a male indicate his reproductive condition.

The two advertising calls of the Great Argus are similarly of low frequency, and are often given from near the top of low hills. These calls are amongst the most evocative sounds of the south-east Asian rain forest, and they can be heard as much as a kilometre away.

The daily pattern of calling during this period typically has a peak around dawn, and in some species a secondary peak at dusk. This has been qualitatively stated for many *Francolinus* species, and there are limited data for the Swamp Francolin which show a peak around sunrise and sunset. Male Koklass Pheasants chorus in the early mornings from November to June, just as first light appears in the sky. Chorusing appears unaffected by the weather, and usually lasts about half an hour, finishing before sunrise. The Cheer Pheasant, which also occurs in the Himalayas at mid-altitudes, choruses at dusk as well as dawn. Both sexes of this monogamous species participate in the chorus, the paired male and female usually calling together in such a way that it sounds as if only one individual is giving a very complex call. First calls are usually given an hour or

less before sunrise, and may, on occasion, last up to an hour after it. In the evening, the chorus typically lasts from up to an hour before sunset to half an hour afterwards.

As these sounds are conspicuous to the human ear, they are often the first indication that a particular species is present in a given area. Therefore, knowledge of these loud calls provides the most ready form of identification in many circumstances and is an important survey technique when searching for many species which are little known or difficult to detect. This has proved especially valuable in the cases of the Koklass and Cheer Pheasants.

Other breeding season vocalizations that have been described include nest and courtship feeding calls and post-oviposition cackling. Nest calls are given by some females when on the nest, as in the Rock Partridge, these are soft notes that rise and fall. Courtship feeding calls are emitted by most species and are believed to result from "stimulus contrast", whereby novel food items elicit a greater response than do familiar ones. There is relatively little variation among pheasant species in the structure of this feeding call, while there is more diversity in form among the partridges, quails and francolins. Although it might be expected that, as a short range call, there might not be much need for species-specificity in these calls, it has been suggested that such differences that do exist throughout the family as a whole are the result of selection pressures arising from the body size of a given species and the habitat in which it lives.

The post-oviposition cackle of the female Red Junglefowl is believed to incite competition between males for the female. The cackling, usually uttered within an hour of laying, is believed to coincide with ovulation and, by inciting competition between males, it appears that dominant males may be most likely to fertilize the eggs.

As well as this array of vocal signals, some phasianids also make noises by flapping their wings rapidly. "Wing-whirring", as it is known, appears to be designed to create sound, and is used during courtship display by male gallo-pheasants (*Lophura*). The level of sound produced by this display varies, at least in the Crestless Fireback (*Lophura erythrophthalma*), and may be virtually inaudible at five metres, or may carry up to 30 metres.

Food and Feeding

There is considerable variation among the phasianids in terms of diet. Kinds of food eaten vary between groups and also by season, and even by habitat in some species, but in most cases food is found just above or below ground level. Food taken includes a wide variety of seeds, leaves, flowers, stems, buds, tubers and roots of different plants, and many animals, from larval forms through invertebrates to small reptiles, in some cases. Whilst there is much information on the diet of phasianids in Europe, including introduced populations, and in some instances in South Africa, detailed data are lacking for most other areas. In these latter regions, such as the Himalayas and south-east Asia, all that is known is what has been gleaned from occasional observations and what has been found in the stomachs of birds shot, usually by the sporting naturalists of times gone by. Hence, all that is known about the diet of Finsch's Francolin (*Francolinus finschi*) is that it includes beetles, insect larvae and seeds, while the food of the Moorland Francolin is not known at all, although it is expected to consume mainly bulbs and roots in a mixed diet. Very little, if anything, is known about the feeding habits of most galliform inhabitants of south-east Asia's forests, such as the Brown-breasted Hill-partridge (*Arborophila brunneopectus*) and the Siamese Fireback (*Lophura diardi*).

In contrast, the diets of several European species are rather well known, with the Grey Partridge among the most extensively studied. Not only has a list of food items been compiled, but how this varies through the seasons, especially during breeding, and over its range has received much attention. Introduced populations of the Ring-necked Pheasant, a native of temperate Asia, have been widely studied in many parts of Europe and North America.

Despite the great contrast in the detail available, it seems fairly safe to say that there are species which are almost exclusively vegetarian and others which feed mainly on animal matter. Chicks of most species are insectivorous, but some require greens. Confirmed vegetarians appear to be those pheasants and partridges which inhabit high latitudes or altitudes, such as the snowcocks (*Tetraogallus*) and the Snow Partridge, which are also amongst the most northerly dwelling

Although it avoids wet areas and heavy forest, the range of habitats occupied by the Chukar is quite wide, including forest clearings, hillsides up to the snow-line, slopes with bushes and trees, dry valleys, arable fields, bare stony slopes and deserts. The races which live in the most arid areas, such as this bird, are normally paler than those which inhabit damper areas, with sandier, less vinous, brown upperparts and a purer grey crown and hindneck. Differences have been observed between populations of a single subspecies, the plumage varying to resemble the colour of the local substrate.

[*Alectoris chukar sinaica*, Israel.]

members of the family. The Caucasian Snowcock, for example, eats almost exclusively plant material, consuming leaves, fruits, seeds, stems, bulbs and tubers of various plants, 65 species of which have been identified from stomach contents. Grasses and the like, such as *Poa*, *Festuca* and *Carex*, are predominant, comprising nearly 40% of the total weight of material consumed in late spring and summer and over 40% during the rest of the year. Legumes, including *Oxytropis*, *Astragalus* and *Trifolium*, make up just over 30% of the diet during these two periods, with a slightly higher proportion in winter than in summer. Some insects are reportedly eaten, but the amounts are tiny for both adults and young. Whilst the plant species taken remain broadly similar throughout the year, the parts that are consumed vary according to season, being new shoots during the spring and summer and tough parts of the plant at other times. Chicks eat similar foods, but over half of the diet is taken up with legumes, while grasses comprise well under a fifth of the total weight of plants eaten. It has been suggested that this is one way in which the young may receive protein in the absence of an insect component to the diet.

Other vegetarians include the Snow Partridge from south-west China, for which 43 plant species have been recorded from 12 individual birds, and some of the Himalayan pheasants. The Koklass Pheasant from the mid-altitude forests is believed primarily vegetarian, as is the Blood Pheasant, a resident of the upper forests and alpine areas. Indeed, the eminent pheasant naturalist W. Beebe in his monograph quoted a colleague as reporting that some birds he shot were almost inedible because of the flavour of turpentine, a consequence of a diet of recently sprouted juniper and fir shoots. The diet of the Blood Pheasant is believed to be based on opportunism, varying considerably throughout the year according to what is available and not hidden under snow and ice. It is always, however, plant material, such as fir and juniper shoots, berries, mosses and their spore cases, bamboo leaves and, not surprisingly, the reproductive parts of plants as they emerge in the spring.

At the other end of the scale are those pheasants and partridges which may be almost entirely, if not exclusively, consumers of small animals, mainly invertebrates. These are typically inhabitants of rain forests in the tropics. Information is, however, very patchy, and as more observations are made

it is becoming increasingly apparent that many of these species which were thought not to eat plants, do actually eat fruits and other parts on occasion, and are better considered opportunist feeders. Part of the reason for this misunderstanding is that the dense habitat in which they live, and the secretive nature of these tropical forest species means that it is extremely difficult to discover any details of their ecology. For example, it has been written that the Malaysian Peacock-pheasant and the Crested Wood-partridge do not consume much, if any, vegetable matter. A few observations of foraging birds and examination of droppings by G. W. Davison has shown that whilst many different invertebrates are indeed eaten by tropical forest phasianids, fruits, seeds, leaves and the like are also included in the diet.

Given that a food source such as termites may be very locally distributed on the forest floor, it could be assumed that if a bird comes across a moving column, or a termite mound, it might feed almost exclusively on termites, or ants or whatever may be locally abundant. However, the very fact that these types of food are often unpredictably distributed means that specializing on them might be risky, especially when the abundance of invertebrates seems to fluctuate so much from place to place and through time, for reasons that are not yet understood. Understorey plants that tropical forest pheasants and partridges are known to eat include those that bear berries, such as *Aglaia*, and palms (*Calamus*). Remains of corollas, rootlets and fibres, mosses and ferns have all been found in droppings. It is most striking that taken singly, each food item of these tropical forest species accounts for only a very small part of the diet, or has been seen taken only once or twice, with the exception of the odd instance when a bird has gorged itself on termites or ants. This may reinforce the belief that the birds are forced to be rather general in their choice of food. Indeed, it has been suggested that constraints imposed by diet have a major effect on reproduction in the Great Argus and Malaysian Peacock-pheasant.

Interestingly, whilst the diet of those African species which live in the interior of the forest are poorly known and plant parts are listed in among their food items, the only forest francolins for which there is any estimate of the importance of particular categories of food give conflicting information as to

The two species that form the genus *Ammoperdix*, the Sand Partridge and the See-see Partridge (*A. griseogularis*), are the phasianids best adapted to arid habitats, including even hot deserts. Unlike the *Alectoris* partridges to which they are clearly related, both *Ammoperdix* species show clear sexual dimorphism, only the male having the white patch on the ear-coverts and the longitudinal streaking on the flanks.

[*Ammoperdix heyi heyi*, Israel.

The Tibetan Partridge is amongst the phasianids that occur at the highest altitudes. In summer it is normally found between 3600 m and 4600 m, in areas where there is a certain amount of grass or bush cover, but it is sometimes seen in bleak areas up to at least 5600 m, very close to the snow-line, where little food or cover can be found. The white chin, the conspicuous large black mark below the eye, and the chestnut collar clearly differentiate this species from the other members of the genus *Perdix*.

the prevalence of each in the diet. Arthropods, particularly *Basidentitermes* termites and *Psalidomyrmex* ants, comprise up to 90% of the diet of Latham's Francolin in the rain forests of West Africa. Other insects, including larvae, and snails are also taken and the other 10% is made up of a variety of plant material, principally fruits but also seeds and green leaves. In contrast, the Scaly Francolin, an inhabitant of equatorial rain forest, is probably primarily vegetarian, and eight birds from Zaire were found to have eaten little in the way of animal material.

Most of the African francolins from open and semi-open habitats are considered to have a mixed diet, taking both animal and vegetable matter. In some Grey-winged Francolins from Natal, South Africa, 70-75% of the volume of the crop contents was made up of bulbs and roots, particularly those belonging to the families Iridaceae, Amaryllidaceae and Cyperaceae, while 20-25% consisted of insects and other invertebrates, in summer most notably grasshoppers, ants and beetles. The remainder was made up of seeds, fruits and other plant matter.

Many of the species which inhabit these non-forested or forest edge habitats have proved capable of surviving in cultivated landscapes to some degree. In some cases, however, agricultural practices have been intensified beyond the tolerance of a species, as in the Grey Partridge of northern Europe. The cultivated lands that are most commonly inhabited are various sorts of crops, where fallen seeds are consumed along with insects living on the crop plants. Japanese Quails, for example, are omnivorous with a diet consisting mostly of seeds of weeds in cultivated areas, and also the gleanings of cereal crops. Seeds eaten include those from arable land weeds, such as chickweeds (*Stellaria*, *Cerastium*), fat-hen (*Chenopodium*) and dock (*Rumex*), as well as grain from millet (*Panicum*), wheat (*Triticum*) and oats (*Avena*). Several francolins also enter cultivation to feed, but most tend to pick up fallen grain and insects from the ground, and, like the Japanese Quail, do not damage crops.

When considering the diets of pheasants and partridges, the most striking conclusion is that the present state of knowledge is very poor. For example, whilst the diet of introduced populations of Ring-necked Pheasants is fairly well known, there is much less information from most of its natural range. As with

vocalizations, much of what is known is the result of anecdotal observations, and this has given a list of what each species will eat. When and in what proportions various foods are consumed generally remains to be investigated, and in a conservation context this means that in most instances even the basic dietary requirements are not known.

About the only conclusion that can be drawn from the information gathered so far is that whether phasianids are herbivorous, insectivorous or omnivorous depends to a large extent on their habitat. In areas where there are probably relatively few invertebrates around as potential food, such as high mountains and north temperate areas, birds eat a high proportion of plant food. Tropical rain forest, however, contains a wealth of small animal prey types, and these are of much more significance in the diet than is the case in other habitats. Although many more animal food items are consumed in such regions, there are likely very few, if any, totally insectivorous phasianids in tropical forest, which probably goes back to the fact that the supply of food is not predictable in time or space. The apparently haphazard distribution of insects in this rich and diverse habitat appears to be the result of complex and, as yet, poorly understood population dynamics.

Detailed information on the diet of phasianid chicks is even more sketchy than on that of adults. However, what is known points to the young being heavily reliant on insect food in the early stages in most cases. Most attention has been paid to the Grey Partridge in Europe, probably as a result of its importance to local economies through shooting activities. The role of diet in chick survival has exercised many partridge biologists throughout the species' natural range, and also where it has been introduced in North America. Whereas insects are believed to be only of minor importance to the adults, they are vital to the survival of chicks. Studies conducted in different parts of Europe in different seasons indicate that insects normally comprise at most 16% by volume. In contrast, up to 95% of the food items eaten by chicks in the first week of life are insects, and 80% over the first two weeks, primarily Coleoptera such as weevils, leaf beetles and knotgrass beetles, although there is much local variation. Ant pupae, insects from hay fields, aphids, plant bugs and sawfly and Lepidoptera caterpillars

The Grey Partridge lives in flocks for seven or eight months of the year.

The family group, or covey, may be joined by some unsuccessful breeders, or two family groups may gather together. In the autumn and early winter months, flock size usually averages 10-15 birds, dropping to 5-7 by the end of the winter or early spring, due to both mortality, normally higher during winter, and the departure of paired birds.

Coveys are fairly sedentary during winter, even in severe weather conditions, unless the amount of snow is such as to make grain or other food unavailable.

[*Perdix perdix*.

Photo: Richard Vaughan/
Ardea]

are all important at some stage in various areas. Some insect groups are avoided, such as thrips, carabid beetles, swift-fly-flies and parasitic wasps.

There are a few striking exceptions regarding the chicks' requirement of insects in order to grow healthily. Snowcocks from the upper slopes of high mountains in Europe and Asia are almost exclusively vegetarian, and this appears to be true of chicks as well, although, as noted above, they take far higher proportions of leguminous plants and far fewer grasses.

Information on seasonal variation in diet is restricted to a few species. The Grey Partridge consumes more insects during the summer months than in winter, when they comprise a negligible part of the diet. It seems likely that, once again, the kind of food taken will reflect what is most readily available at a particular time, in most cases. In south-east Asian forests, the presence of some food sources is not predictable. For example, some tree species do not flower and fruit on an annual cycle, and figs (*Ficus*) are markedly aseasonal in their flowering patterns. This seems to mean that particular items among both these potential food types and also the invertebrates that feed on them are available to the local pheasants and partridges on an irregular basis.

Most phasianids feed on the ground, although some may climb into bushes or even onto low branches of trees. The Satyr Tragopan, for example, takes leaves, moss and berries from species such as *Berberis*, *Symplocus* and *Rhododendron*. The other tragopans and the Blood Pheasant are also arboreal to some extent. In the main, however, foraging is done at ground level, and ranges from snapping at insects to gleaning seeds and turning over leaf litter, to digging over the ground to reach roots and tubers.

The bills of some of the pheasants, in particular, have attracted comment on their suitability for excavating large areas of soil in search of food. The strong bills of the monals, the Cheer Pheasant and the eared-pheasants, for example, are all ideal for digging up various foods found below the soil surface during part of the year at least. These species characteristically feed on tubers, roots, bulbs and subsoil invertebrates, and large areas of dug-over soil are typical signs of their presence. The Cheer Pheasant tends to feed on these subterranean foods in the winter when other items are unavailable.

As well as digging, Cheer Pheasants have been observed pecking at vegetation near the ground and browsing on shrubs and tall grasses and other plants that appear seasonally. The most intensive study of the species conducted to date showed that browsing was the least common of these methods. Females spend more time feeding than do males, spending about 70% of their time looking for food, compared with the figure of just over 40% that males devote to foraging. Whilst both sexes spend more time digging and picking up items from the exposed soil than they do pecking at vegetation, this difference is far greater for the females, which may spend the vast majority of their time digging.

Tropical forest species generally appear to have less stout bills and to feed by turning over leaf litter, either with the bill alone, or using their feet to scratch away as well. Birds then peck at the exposed soil surface, picking up various foods, including invertebrates such as *Campanotus* ants. In Malaysia, it has been suggested that the foraging technique that a species uses ties together its dispersion with that of its invertebrate prey. For example, the Crested Wood-partridge, and the Crested and Crestless Firebacks, all species that often form groups, tend to scratch at the leaf litter so that they can take the invertebrates that live underneath this layer. These invertebrates are often small colonial species, and when one of the birds finds food, the other members of the flock come to feed beside it on the abundant supply; clusters of fallen fruit also attract such flocks. Solitary species, such as the Great Argus, do not tend to use their feet much, simply picking up items from the surface of the litter, rather than from underneath it. Their invertebrate prey seems to be confined to single larger animals, such as large ants and bugs, which are walking alone.

Obviously, foraging is an important part of the daily routine of the phasianids (see General Habits). Outside forested habitats, it most typically occurs in the early morning or late afternoon. This is often because of the midday heat of the tropics and subtropics, but the presence of potential predators has been suggested as a major determinant of Chinese Monal's feeding times during winter: on fine days up to ten birds of prey have been recorded circling overhead in the middle of the day.

Breeding

There is a considerable diversity of breeding patterns exhibited by the phasianids, including monogamy, and both simultaneous and sequential polygyny. Whilst D. Lack reported that just over 90% of all bird species are monogamous, there is a disproportionate number of non-monogamous species among the Galliformes. Indeed, nearly one third of the genera in the Tetraonidae, Meleagrididae, Odontophoridae, Phasianidae and Numididae are believed to be typically polygynous or promiscuous, a much greater number than among birds in general.

As phasianids produce nidifugous chicks, which can move about very soon after hatching and feed themselves, the parents do not have to find food and bring it back to nestlings, as is the case in most other bird families. Therefore, parental responsibilities are confined to brooding the chicks, guiding them towards food sources, and watching for predators. These are all activities that one adult can perform adequately, and the presence of a second adult rarely doubles the effectiveness with which these duties are carried out. This means that, in some cases, the presence of males may not prove especially beneficial to chick survival, and, as a consequence, the family group consists of only the adult female and the chicks. The result is a shorter pair-bond between male and female, which allows males to try and attract other females for mating. In this situation, many males might be competing for mating opportunities with relatively few females, resulting in fairly intense selection pressure being exerted on any heritable male trait that will improve a male's chances of attracting a mate. Such traits might be morphological or behavioural, and might include more extravagant plumages or better fighting ability.

In the early 1980's M. Ridley reviewed what was known about mating systems in the pheasants, partridges, quails, snowcocks and francolins, and also in some other Galliformes. Although some new information has been added, many of the generalizations remain pertinent. In monogamous species, the pair-bond usually lasts at least for one whole breeding season, and both parents help to raise the young. In some instances, the male may also share incubation duties with the female. Amongst those perdicines for which there is any information available, monogamy is found in virtually all genera, whereas

about half of the pheasant genera are probably non-monogamous.

Most of the African francolins are believed to be monogamous, as they have been seen in pairs during the breeding season, and the only exceptions, for instance the Grey-striped Francolin (*Francolinus griseostriatus*) and Handsome Francolin, are too poorly known to admit even suppositions as to what their mating systems might be. In monogamous francolin species, the pair-bond may last more than a single season. The duties of the sexes have been studied in several species, usually those from open habitats, where observation of birds is considerably easier than in forests.

The Rock Partridge of southern Europe, along with other *Alectoris* species, is monogamous, but instances of successive bigamy have been reported. Pairs form from February onwards, as winter flocks begin to break up into smaller groups. From March and April, pairs establish territories, often using the rally call, the function of which varies according to season; it is mainly used for territorial assertion during spring. Females are believed to lay only when all boundary disputes have been settled. Whilst males are believed not to assist the female in the incubation of the eggs, some males have been found with brood patches. The male usually, however, attempts to maintain the integrity of the territory during incubation. The size of the males' territories appears to bear some relation to the structure of the winter flock, whereby the most dominant males obtain the largest areas, but availability of cover and food and the density of the population all influence this association. If, however, a second clutch is laid, the male incubates this alone, which may account for the presence of brood patches in some individuals. When the chicks hatch, the females raise the brood on their own, the males forming small, single-sex groups.

Non-monogamous mating patterns observed in the Phasianidae include both simultaneous and sequential polygamy. In the former, each male pairs with more than one female at the same time, whereas in the latter, a male pairs with one female after another. Simultaneous polygamy is also known as harem polygamy and is seen in several species, such as the Red Junglefowl and Lady Amherst's Pheasant, while the Ring-necked Pheasant is the best known example, by virtue of the study of its introduced populations.

The Blood Pheasant is a species associated with the margins of conifer or rhododendron forest, roosting in the interior and coming out into the open to feed. One of the few occasions on which the species flies is to reach its roost, as it generally prefers to escape from danger by running. This is the smallest of the pheasants and its rather short tail and overall appearance suggest a colourful francolin. Unlike most francolins, however, this species is highly sexually dimorphic in plumage, the female being mainly brown. The Blood Pheasant is generally considered to represent some sort of a link between the partridges and the pheasants.

The Indian Peafowl climbs trees during the day to rest or to hide from danger, and it will also do so at night in order to roost. Birds often choose the top branch of a dead tree, apparently impervious to bad weather, even on nights of heavy rain. The huge train, which can make up 160 cm of the bird's total length of about 230 cm, makes this species one of the largest birds capable of flight. Contrary to appearances, the highly ornate and surprisingly light-weight train is not formed by the rectrices, which are dull coloured and of moderate size, but by the 100-150 uppertail-coverts, each of which has long, disintegrated barbs and a large subterminal ocellus.

[*Pavo cristatus*,
Sri Lanka.

Photo: Alfred Limbrunner]

The Ring-necked Pheasant tends to be found in single-sex flocks during the winter, though this depends to some extent on the availability of suitable habitat. The two sexes appear to use different habitats during the winter, the females inhabiting woodland with a shrub understorey, and males using scrubby areas such as hedges and woodland edges. Females disperse from their winter flocks during late March and early April, when average flock size falls from six to two birds. Large overlapping winter ranges within woodland are replaced by widely separated breeding ranges in more open habitats. Males also move out into more open areas, taking up territories which encompass the edges of woodland. During dispersal, females, usually from the same winter flock, continually join and leave harems. The number of females to be found with each territorial male can vary considerably, some males obtaining many females, with up to 18 reported, whereas others may attract very few, if any. Nest-site selection, incubation and the raising of the young are all carried out by the female alone, while the male continues to defend his territory and display to females that are not sitting on eggs. Once all the females in a harem have nested, the male may cease the defence of his territory and eventually abandon it.

Conclusive evidence that sequential polygamy is the main reproductive strategy for any phasianid is lacking, but it is believed that the male Satyr Tragopan remains with the female only until the onset of egg-laying, or very early incubation at the earliest. The system is, however, known to occur occasionally in several species, such as the African Blue Quail (*Coturnix adansonii*). In this species, in places where the sex ratio may favour successive polygamy, the female incubates the eggs and tends the chicks on her own, whilst the male is presumably left free to mate anew.

Promiscuous pheasants appear to have one of two mating patterns, which are described in terms of the dispersion of males: promiscuity with aggregated males; and promiscuity with dispersed males. The only pheasants in which the males gather together in groups to display to females are the two Asian peafowl. Whilst the display dispersion of male Green Peafowl is poorly known, the Indian Peafowl, a common sight throughout much of south Asia and in many parks and gardens

elsewhere in the world, has been the subject of a fair amount of study, in both India and the UK. The dispersion of the males does appear variable according to local conditions, but in general they tend to be clumped together. Harem polygyny has also been reported for both of these species.

The clumping of peacocks to display to females falls within the dispersion pattern that has been described as a lek, a collection of males that are drawn together simply for the purpose of attracting females with which to copulate. In India, breeding seasonality varies according to the onset of the wet season. Each male establishes a territory in close proximity to other males. These territories are defended by threatening or attacking intruding males, and visiting females are displayed to. Females seem to wander through the various territories on the lek, sometimes singly and sometimes in groups, and they may move between the different clusters of males. A study of the feral population resident at Whipsnade in southern England revealed that females may visit several different males in a lek, and revisit a preferred male, possibly many times, before finally copulating with him. Of eleven occasions when a female's path through the lek was monitored in detail, she mated with the male that had the most eye-spots on his train ten times. After copulation, the females nest, incubate and rear the young without the assistance of a male.

Promiscuous species in which the males are dispersed rather than clumped together during the breeding season include the Malaysian Peacock-pheasant, the Great Argus and the Crested Argus, all inhabitants of rain forests of south-east Asia. Males of all three of these species make display scrapes, which are also referred to as "dancing grounds"; they clear leaf litter from a small area of the forest floor, so that the bare earth below is exposed. Studying these secretive rain forest species is not easy, but the spacing patterns of males has been documented in some detail.

On Gunung Rabong, a mountain in Peninsular Malaysia, Crested Argus males were heard calling within a narrow altitude band at 600-900 metres above sea-level. The calling males appeared to be a minimum of a half a kilometre apart, but, whilst their calls do carry that distance, birds are not in visual contact when on their display areas. In the closely related Great

Although the Grey Partridge's main habitat requirement is the presence of areas of continuous grass or herbage, it also requires access to areas of bare ground where the bird can dust-bathe. The bird first lies down on the ground, then scratches up dust or sand into the plumage with its feet, and throws it up onto its back with its wings, before finally shaking it out. Such behaviour helps to keep the plumage in good condition, mainly by removing excess preen oil, dry skin, feather debris, and the like.

Argus, only adult males are believed to maintain such cleared areas in most years. Females were seen visiting males on their display sites, which are typically widely spaced on small hills in the lowlands, and it has been suggested that females roam through the forest visiting various males that are in possession of display sites. The male's display is quite extravagant, to the human eye at least. Following copulation, as in the Indian Peafowl, the female is responsible for the incubation and all the parental care, while males continue to call and maintain their display sites.

Why is there such a diversity of reproductive patterns among the pheasants? Two of the suggestions put forward are closely related to habitat: food availability; and habitat structure. In the first, it is thought that competition for patchily distributed items of animal prey in tropical forest has resulted in largely insectivorous tropical forest species adopting a solitary lifestyle. In contrast, open country species tend to feed on widely distributed foods, such as grains and other seeds, together with invertebrate prey that is similarly widespread. The second proposal, that related to habitat structure, centres on the need for mate guarding. In open country habitats there is little concealing vegetation, and females can be observed relatively easily by both predators and conspecific males, which leaves them open to attack by the former and harassment by the latter. Therefore, long pair-bonds have resulted, whereby a

male guards the female from unwanted attention. Where females remain gregarious throughout the breeding season harem polygyny has evolved because a single male is able to guard more than one female at a time. In the denser, closed habitats, females are more effectively concealed by the dense vegetation, and, as a consequence, are not bothered so much by predators and conspecific males. There is, therefore, less need for mate guarding by the males, and this has led to shorter-lived pair-bonds, such that in the extreme the pair-bond lasts for the duration of copulation only. The final stage in this proposal is the movement of promiscuous species from the forest back to open or semi-open habitats with an attendant shift from solitary to gregarious breeding habits.

The degree of sexual dimorphism that is so variable throughout the family (see Morphological Aspects) appears to be associated with the mating pattern in a given species. H. Sigurjónsdóttir reviewed the degree of sexual size dimorphism in relation to colour dimorphism and the extent of parental care in 89 species of Galliformes for which data of varying quality could be obtained. This revealed that the sexes were alike in monogamous species in which the male assists in the care of young, whereas the sexes differed, sometimes strikingly so, in polygynous and promiscuous species in which the males plays no part in rearing the offspring. Sigurjónsdóttir concluded that sexual dimorphism among the Galliformes, which are herbi-

vorous and omnivorous and have precocial young, is the result of sexual selection. Increased dimorphism in both size and colour, as well as the development of other special characteristics, in both polygynous and promiscuous species, is believed to be the result of increased selection pressure on the males to gain mating access to the females. A male that does not form a long-term pair-bond with a female has the opportunity to mate with more than one female, and therefore competition between males for mating opportunities is, potentially, fierce.

Pheasants have long been thought of as examples of sexual selection, but with no firm evidence to support this, until recently. The aforementioned Whipsnade study of the Indian Peafowl shows that the more extravagant a male's train, the better his mating success. A separate study indicates that the train increases in splendour as the male ages, implying that females are able to choose to mate with older males, which have demonstrated their ability to survive. Of course, alternative explanations for these observed patterns of behaviour abound.

In most species the timing of breeding is believed to be governed by the seasons, be they the four seasons of the north temperate regions, or the wet and dry seasons of the tropics. Throughout the Palearctic and along the Himalayas, the beginning of spring sees the commencement of breeding activity. The exact timing depends upon the latitude and also the altitude of the locality. For example, southerly *Alectoris* partridge populations begin laying between late March and late April, whereas egg-laying in the snowcocks, which are inhabitants of upper mountain slopes, begins in late April at the earliest.

In these relatively high latitude species, winter dispersion patterns break up prior to egg-laying, as courtship commences and nest-sites are chosen. In the Altai Snowcock (*Tetrao gallus altaicus*) winter coveys of up to 35 individuals split up during March, when pairs form and leave the group. Older birds are believed to begin nesting earlier than younger ones. Both sexes become aggressive, and fights between pairs are common. Nests are made on south-facing slopes and are built by females.

Such direct information on the timing of breeding is lacking for most Himalayan species because of the difficulty in seeing

birds, let alone watching their courtship and finding their nests. There is some information on the duration of the calling season in some species, however. Four pheasants from north-west India are most readily detected by their vocalizations, namely the Koklass and Cheer Pheasants, the Himalayan Monal (*Lophophorus impejanus*) and the Western Tragopan (*Tragopan melanocephalus*). The first three are all calling by the end of January or the beginning of February, whereas the Western Tragopan does not appear to call at dawn until late March or early April. All four call until the beginning of June, and the Cheer and Koklass also chorus at dawn in the autumn and winter months. The role that calling by the male plays in the breeding cycle is likely to vary according to the species. For example, it may be that Koklass Pheasants need to call through much of the year in order to maintain territories, while Western Tragopans only set up territories in the spring and call to establish themselves and attract mates.

Further west, the species inhabiting the arid zone of the Middle East also breed, in the main, in the northern temperate spring and summer. Thus the Sand Partridge (*Ammoperdix heyi*) and the Arabian Partridge (*Alectoris melanocephala*) begin laying sometime during March or April in Oman and Jordan, depending on locality and species.

The widespread African francolins breed in various months in the different parts of their ranges, usually coinciding with local wet seasons, although Shelley's Francolin (*Francolinus shelleyi*) breeds during the dry season, whenever that may be at any given locality within its patchy distribution. The widespread Red-necked Francolin (*Francolinus afer*), for example, breeds in the late wet or early dry season, ensuring that there is a flush of vegetation following the rains. This means that somewhere in its range it is breeding at any given time, be it from March to June in Angola, January to August in Malawi, or in all months except August to October in Zimbabwe, to consider just three range countries.

The seasonality of tropical rain forest phasianids in south-east Asia is the most poorly known in the family. The little information that exists points to regional patterns that are very different from those elsewhere. Two separate studies, of the Malaysian Peacock-pheasant and the Great Argus, have suggested that individuals are unlikely to breed every year. Based

The crow of the adult male Red Junglefowl is surely the best known of all bird calls. Its function is often territorial, the bird crowing from the roosting site before dawn, and also during the day whilst it patrols territorial boundaries or if other males encroach. Other functions of crowing include: a prelude to mating; a proclamation of dominance over subordinate birds; gathering the flock together after feeding, when the birds are ready to move on; and, after checking that there is no danger, informing the flock that it can safely cross open ground.

The advertising call of the Coqui Francolin is made up of a series of 7-10 trumpet-like notes, the earlier ones being the loudest, and the later ones weakening. This call is normally made in the early morning, at midday and in the late afternoon, although at the onset of the breeding season it is generally heard much more often. This species' other characteristic call, which is uttered throughout the day, is a repeated series of two high-pitched, squeaky notes, "cô-qui, cô-qui, cô-qui", which have given the bird both its scientific name and its common name in several languages. This calling bird clearly shows the feature which best distinguishes the male of this species in the field, namely the rather uniformly ochre coloured head and upper neck, sharply separated from the barred lower neck and upper breast.

Whilst the Brown Quail can satisfy its water requirements from insects and other invertebrates with which it supplements its basic diet of grasses and other small herbs, it can sometimes be seen drinking at water-holes and streams. It shows a certain preference for swampy habitats, and frequently inhabits fringes of freshwater wetlands, floodplains, salt-marshes along seashores and backwaters of artificial wetland habitats. The three birds with coarser black markings on the upperparts are females.

on circumstantial evidence, it was concluded that food availability is the major constraint on reproductive efforts in these two species. The availability of food for these birds does not appear to be under the regulation of an annual cycle, but it might be strongly influenced by mast-fruiting years. In these years, which may occur from five to ten years apart, many tree species flower and fruit simultaneously, and invertebrate populations increase as a result. Consequently, there is much food that is potentially accessible to the pheasants. Numbers of calling male Malaysian Peacock-pheasants were much higher in one such year, as were the number of maintained display scrapes. If this proposal is correct, then breeding periodicity is not seasonal in these species, but may span several years, and may vary from one individual to another, depending upon the ability of each to secure food resources.

Whatever the breeding periodicity, the beginning of the reproductive period is marked by courtship, which may involve both visual and vocal displays. In many cases, it is not known how males and females come together. Calls by males, assumed to be advertisement calls, are reported during part of the year for many species. In some cases, such as that of the Grey Partridge, if both members of a pair survive till the next season they will reunite while still in the winter covey. It is more common in this species, however, for birds from different groups to pair up in advance of nesting, possibly up to four months beforehand.

Males of many species advertise their presence by calling. The dawn crowing of Red Junglefowl, or domestic cockerels, amongst other species, is well known throughout the world. Variation in vocal behaviour between individuals in phasianid populations has received scant attention. One study has, however, shown that there may be considerable difference between individual male Malaysian Peacock-pheasants in both the rate at which they call and also the type of loud call that they give, and similar variation among males of the Great Argus has also been reported. In dense rain forest, vocal signals may well be the easiest method by which birds can locate conspecifics, and vocal displays may therefore be of considerable importance. Not all species, however, call loudly at the onset of the breeding season, and several tropical forest pheasants and partridges are quiet for much of the time. The Crestless Fireback, for example, has no known loud crow.

The visual displays of some of the pheasants are very striking and have received much attention in popular books and articles. As with vocal displays, however, there have been few attempts to investigate these behaviour patterns in detail. Many

of the various display postures have, however, been described, and the full-display repertoires of many species are known, often from observations of captive birds.

Many of the phasianid displays have typically been categorized as frontal or lateral, descriptions which refer to the orientation of the male to the female whilst either posturing or moving. Lateral displays often involve the spreading of wings and tail in such a way that the bird appears larger when viewed from the side. For example, the wing nearer the female may be dropped so that the primaries are close to the ground, while the wing further away is raised, as in the Palawan Peacock-pheasant. The tail may also be spread in the vertical plane, whether it is compressed, as in Bulwer's Pheasant, or not, as in the Malaysian Peacock-pheasant.

In frontal displays the male faces the female, and when spreading the wings or tail, tends to do so symmetrically. Male Silver Pheasants and Temminck's Tragopans (*Tragopan temminckii*), for example, face their respective females and rear up when opening the wings, which they beat either rapidly, as in the "wing-whirring" element of the former's display, or slowly, as the latter does when wing flapping.

As well as the lateral or frontal orientation of the wings and tails and movements, many of the display elements also involve inflating, raising or exposing various parts of the body, such as wattles, ruffs or lappets so that they are shown to the female to the maximum extent and effect. Hence lappets, which unfold under the throat, are shown during frontal display in the tragopans, and wattles, which expand above and below the side of the head, for example in Bulwer's Pheasant, are mostly inflated during lateral display.

Whilst many of the display elements can be grouped into one or other of the two directional categories, males of some species exhibit both lateral and frontal display at one time or another. Male Grey Peacock-pheasants (*Polyplectron bicalcaratum*), for example, may either face the female or stand side on to her. In the frontal display, the male lowers the head and breast towards the ground, and raises and spreads the tail, so that it appears relatively vertical. The head is usually slanted to one side. In the lateral display, the nearside wing is lowered slightly, the farther one raised, and the tail spread. Both postures present the female with an array of ocelli borne on wing and tail feathers, but one is orientated more vertically than the other. As far as is known, the most elaborate displays appear in the polygynous and promiscuous pheasants, whilst the displays of monogamous species contain fewer separate movements.

Although the Ceylon Junglefowl spends most of its life in forests or dense scrub, it often ventures out to feed in open fringe areas, such as roadsides or glades. This seems to be commoner after heavy rain, and it has been suggested that it is in order to avoid feeding under dripping trees. The species feeds mainly by pecking at the ground, taking grain, weed seeds, berries and other plant matter, as well as numerous insects and invertebrates. This species can most easily be distinguished from other junglefowl-species by its streaked body plumage and the large yellow patch in the middle of its comb.

In the monogamous Swainson's Francolin, for example, males stand upright and, pointing the bill upwards, give the advertising call. The bare red throat skin, which appears to be more richly coloured during breeding, is somewhat inflated. Females reply by standing upright as well, giving a different call that is said to resemble the cry of a human baby. After a couple of minutes of calling, the male chases the female, displaying laterally, rather half-heartedly, and if the female remains, he then displays much more intensely. In this last phase, the head is held upright, the bill pointed forward and the wings fanned so that they are nearly dragging on the ground.

This contrasts notably with the case of the Great Argus, in which the male has ocelli-bearing secondaries that are up to a metre in length and a tail up to nearly 1.5 m long. In this species, males call from widely spaced dancing grounds in the forest. In a sequence watched in the wild, a male descended from a perch adjacent to the dancing ground from where he had been calling, upon the approach of a female. Normally, at the beginning of display in this species, all the feathers of the male's head, neck and body are ruffled, and the male moves onto the dancing ground, walking around the edge with his head held forward and low, and his neck arched. At each step, the male stamps his foot onto the ground, as he circles the female which stands on the dancing ground. The male then continues to walk around the edge of the dancing ground with his tail held increasingly higher to the extent that his body becomes nearly vertical. The male may, sometimes, break into a run around the female in which a cowering posture is adopted, whilst the male trots in arcs with short, rapid steps. Lateral display follows the "Tail-high Walk", and the upper surface of the male's body is tilted towards the female, whilst he runs back and forth. After such a lateral movement, the male swerves to face the female and lowers the head and breast, whilst raising the tail. The wings are spread fully and reflexed at the carpal joints to allow the outer primaries to overlap, giving the appearance of a fan of wing feathers. During the full period of display, the male may switch back and forwards between postures and movements, or occasionally turn with a jump and a wing flap, and run across the dancing ground. "Tidbitting" of various sorts is interspersed between these elements, and its

exact nature varies according to the stage of the display in which it is exhibited. It may simply comprise pecking at the ground, or involve picking up objects and offering them to the female.

"Tidbitting" is a type of ritualized courtship feeding that most male phasianids are believed to exhibit. It typically involves a male either pecking at some food or food-like item, or holding it in the bill and giving a distinctive call at the same time. This often causes a female that is close by to move towards the tidbitting male.

Once courtship is completed and the male has copulated with the female, the search for the nest-site begins, either by the pair together or by the female alone, according to the species. At least one nest has been found of most species, but several are still undescribed, including those of the Grey-striped Francolin of Angola, the Black Wood-partridge (*Melanoperdix nigra*) of Malaysia, Sumatra and Borneo, and Blyth's Tragopan of the Eastern Himalayas. One or two nests are all that have been found in many other species, so generalizations about the nesting behaviour of particular phasianids are not possible in most cases.

Some very broad conclusions can be drawn, however. For example, all known nest-sites are on the ground, with the exceptions of the tragopans which nest on stumps or in trees or bushes up to ten metres above the ground, and the single reported nest of Nahan's Francolin which was placed in the hollow of a tree about a metre off the ground. An interesting case is that of the Swamp Francolin, which inhabits the tall, wet grassland of the *terai* belt along the Indo-Nepal border and north-east India. As it dwells in grass around swamps and standing water it constructs a nest of weeds and wet grass which may be up to 10 cm thick and 30 cm in diameter, with a depression in which the eggs are laid. This structure is built just above the water or mud among fallen and bent reeds, or in other suitable sites in the vegetation of this wet area.

In open country, such as savanna, open bushland and boulder-strewn plains, most nests are found at the bases of tufts of grass or bushes, or next to rocks or boulders. Such nests are typically a simple scrape in the ground, which may, as in the White-throated Francolin (*Francolinus albogularis*) and Hodgson's Partridge, or may not, for example in the Yellow-necked

Francolin (*Francolinus leucoscepus*), be lined with a mixture of dried grass stems, leaves and roots. In a number of cases the amount of lining employed varies from unlined to fully lined within a single species, presumably depending on local conditions and the tendencies of individual birds.

Forest-dwelling pheasants and partridges also seem to prefer a site at the base of some prominent vegetation feature or other. In the equatorial forest belt of West Africa and the lowland forest of south-east Asia respectively, Latham's Francolin and the Crestless Fireback tend to lay their eggs between buttress roots of trees. Whilst the francolin simply lays them on the forest floor without constructing any real nest, the fireback may gather some twigs or similar material together on which to lay. As with open country phasianids, however, the construction of nests can be rather variable within a species. For example, the four known nests of the Malaysian Peacock-pheasant were found: in a shallow depression on top of a termite mound 1.4 m high; directly on the ground among understorey vegetation; in sheltered vegetation against a recent windthrow; and at the base of an understorey tree.

Cabot's Tragopan is the best known of the tree nesting tragopans. Out of 15 nests known, 13 were found in trees within 20 metres of the edge of forest, 10 built in *Pinus taiwannensis* and five in broad-leaved trees.

Once a nest-site has been chosen, the eggs are laid. Clutch size varies considerably through the family, in several cases reaching 18 eggs or more, for instance in the Chukar and the Rock Partridge, the Black Francolin (*Francolinus francolinus*), the Brown Eared-pheasant (*Crossoptilon mantchuricum*) and the Ring-necked Pheasant, although these appear to represent unusual situations, and it is suspected that more than one female may have contributed to the clutch in some cases; the norms for these species are in the region of 7-12 or up to 15. Nonetheless, female Grey Partridges are known to produce even larger clutches, and it has been confirmed that in some instances well over 20 eggs may be laid by a single female. In this species, clutch size increases from south to north and from south-west to north-east.

At the other extreme are the tropical forest species of south-east Asia. Those species for which clutch size is actually recorded lay fewer eggs, and the Malaysian Peacock-pheasant is at present the only phasianid that is known to lay a single egg clutch. The tropical forest gallo-pheasants (*Lophura*) also lay smaller clutches than their more northerly relatives. The Crestless Fireback, for example, lays 4-5 eggs, whereas the congeneric Silver Pheasant on average lays 7 eggs, but up to 12 in south-western China, and the western Himalayan subspecies of the Kalij Pheasant lays 6-9 or even up to 15 eggs.

The suggestion that food supply may well be limiting in tropical forest may also apply to clutch size. Whereas in seasonal regions the appearance of phasianid chicks tends to coincide with annual peaks in food supply, such peaks can not be predicted on a similar time scale in tropical forest. Therefore, the larger clutches of the seasonal climates seem likely to be a consequence of reliable food sources being available on a predictable basis.

Egg size too varies quite considerably, as might be expected from the range of body sizes in adult phasianids. A rough analysis of the ratio of individual egg weights to adult female weights among the pheasants only revealed that eggs weighed from 2.5% to 10% of the adult female's weight. Similarly, the whole clutch comprised upwards of 15% of the female's weight, with the Cheer Pheasant laying a clutch that is alleged to amount to a staggering 63% of the female's weight.

Incubation is usually carried out by the female only. In monogamous pairings, males are concerned with territorial defence during this time, and in non-monogamous pairings, males may attempt to attract other females with which to mate. The shortest incubation periods have been reported as 14 days in the Harlequin Quail (*Coturnix delegorguei*) and 16-18 days for its congeners. In the Indian Peafowl, by contrast, it takes 28-30 days for the eggs to hatch. In most phasianids, incubation takes 18-25 days. When the eggs hatch, synchronously, the eggshells are usually left in the nest.

On hatching, the precocial young are capable of feeding and moving about straight away. The young are led to food

The Indian Peafowl almost invariably goes to a stream or a water-hole to drink after its main feeding periods, early in the morning and about an hour before sunset. After its morning drink, it normally leaves the open plains and scrubland where it finds its food and goes into forest where it will spend the hottest hours in the middle of the day, busying itself much of the time with the tasks of preening and dust-bathing.

The Himalayan Monal lives mainly in forests, but it moves to open areas, such as grassy ridges, meadows and mountain cultivation to feed. Its powerful, strongly decurved bill is designed for digging. It will often spend a fairly long period digging in one place (like two of these three females), when it may dig down to depths of 25 cm or more, to reach the bulbs, rhizomes and tubers that make up much of its diet. This species is commonly found in small groups of three or four birds of the same sex, or of one male with two or three females, although single birds are also seen at times.

[*Lophophorus impejanus*, Sagarmatha National Park, Nepal.
Photo: Joanna Van Gruisen/Ardea]

sources by the parent or parents, and they then peck at food items on their own. Food may be picked up and tossed towards a chick, placed in front of it or even passed from bill to bill. Food calls may be particularly in evidence at this time as adults alert the young to the presence of food items. Chick mortality is very poorly understood, and relevant data are lacking for most phasianids. This aspect has, however, attracted considerable attention in the Grey Partridge.

In this species chick mortality is highest during the first ten days of life, and much of this mortality has been ascribed to lack of sufficient insect food in the intensively farmed regions in which the birds live. Introduced populations of Ring-necked Pheasants also experience high levels of chick mortality, which, it is suggested, may be due to sudden changes in weather causing birds to become wet and cold.

Flight has been reported at only five days old in the Harlequin Quail, and 10-14 days old in the Barbary Partridge (*Alectoris barbara*) and the Red-necked and Yellow-necked Francolins, among others, and this is believed to be fairly typical, although there is little reliable information available for most species. Whilst very young, the chicks may be brooded by their parents.

In the vast majority of species, the behavioural development of the young in the wild is either very poorly known or not known at all. In many open country species, coveys, including young, may be seen for several months and even, in a few instances, right up to the start of the following breeding season. Some family parties join together to form larger coveys, as in the Barbary Partridge during the autumn. One of the functions of coveys is to improve defence. Distraction displays are described for a number of species, including the Harlequin Quail, and are probably fairly widespread throughout the family. One of the adults feigns injury whilst leading a potential predator away from the chicks which hide and remain motionless. Chicks of many species are of adult size by about two months old.

The behavioural development of young chicks has been studied in a feral population of the Burmese subspecies *spadicus* of the Red Junglefowl. Methods of locomotion and feeding are among the earliest behaviour patterns to appear. Chicks are capable of walking, running, jumping and hopping

by the third day at the latest, and hopping soon develops into flight, which does not occur until day 12 in this species. The repertoire of feeding techniques is also rapidly built up, beginning with young birds pecking at objects that contrast with the background. Running with food items occurs from day 2, and scratching the ground begins the following day. Running with food items is possibly a means of attracting other chicks, and the resultant increased attention may ensure that the prey does not escape; it might also develop eventually into tidbitting behaviour. Other feeding-related behaviour patterns include bill-wiping and head-shaking, and these are present by the end of the first week. Various comfort, preening, aggressive and dust-bathing activities all become evident over the following one or two weeks.

When they hatch, the chicks are largely clothed in down, although some feathers of the juvenile plumage may already be present at this stage, such as the first seven primaries. The other primaries appear during the following three or four weeks. The first moult, the post-juvenile, begins shortly after hatching, at about 23 days old in the Ring-necked Pheasant. In this species, it takes 150 days for the primaries and secondaries of the first winter plumage to complete their growth, and 170 days for the completion of all the coverts, whilst the tail feathers grow more quickly.

In those species in which males possess spurs, the timing of the irruption of the spur from the rear face of the tarsus is very poorly known. In the Yellow-necked Francolin, the spurs are apparent at about four and a half months old, and in the Red-billed Francolin (*Francolinus adspersus*) they can be seen from about five months old. It may take up to a year before they become fully grown and sharp.

Most species become sexually mature within the first year, although the adoption of full adult plumage, in males at least, takes longer in a few cases. For example, the train of the male Indian Peafowl takes four years to develop fully, while the male Silver Pheasant assumes adult plumage within two years. Nevertheless, a male Malaysian Peacock-pheasant in captivity has been known to father offspring whilst still in subadult plumage.

Breeding success is yet another aspect that has been relatively well studied in only a few species, and about which

The Grey Peacock-pheasant normally forages slowly and secretively. Even when turning over leaf litter with its bill or scratching the ground with its feet to uncover food, it does it silently. Once the food item is visible, it is carefully picked up with the bill. This species is essentially omnivorous, with food recorded including insects, fruits, shoots, leaves and grubs of many types, as well as rice and grain from village cultivation.

[*Polyplectron bicalcaratum*.
Photo: N. Dennis/NHPA]

virtually nothing is known for the majority. In the Red-legged Partridge (*Alectoris rufa*), a significant factor can be the weather, but it has been found to have different, even opposing, effects in different regions. For instance, in eastern England, rain in June and July can lead to lower overall productivity, as a result of the combination of lower temperatures, increased energy and feeding requirements and lengthier exposure to predators. However, rain during the same period in north-west Spain enhances chick survival, by boosting both vegetation growth and invertebrate availability. Obviously, these differences are closely connected with the contrast between a cool, damp climate on the one hand, and a warm, dry one on the other.

Movements

Whilst phasianids are, for the most part, believed to be sedentary, some are known to perform altitudinal movements, and one genus contains migrants and nomads. Species which undertake altitudinal migrations are those which spend their summers high in the Himalayas or the mountain ranges of China and Europe, and descend to winter at lower elevations, below the snow and ice. Long distance movements are recorded only in the quails (*Coturnix*), some of which are considered migratory, whilst others are thought to be nomadic, or their wanderings appear too complex to understand on present information.

Adequately documenting the extent to which pheasants and their allies move up and down a mountainside is difficult. In most cases, it is only possible to make generalizations from records of the altitudes at which occasional observations have been made in various seasons and at various places. Knowledge of the altitudinal range which individuals or even populations inhabit in each season is largely lacking for most species, so an understanding of the timing of such movements is even more remote.

Amongst the studies to have yielded most data on this aspect of phasianid ecology is the Himachal Wildlife Project, a series of surveys led by A. J. Gaston, P. J. Garson and M. L. Hunter between 1979 and 1983 in several parts of the north-west Indian state of Himachal Pradesh. During this project, 73

records of the Himalayan Monal were made between 1800 m and 3500 m. During December and January birds were encountered from 2100 m to 3300 m, with most records above 3000 m. They moved down in February and March, being found as low as 1700 m and up to 2900 m, with most records at 2300 m in the former month and above 2500 m in the latter. There was a considerable upward movement in April, when most birds left the low altitude coniferous forests for the oaks at higher elevations and were spread from 2000 m up to 3500 m, where they reached the tree-line. Continuing to climb, birds venture above the tree-line onto the alpine meadows beyond, during May, when few individuals were found below 2700 m, and most were in the upper forests and areas straddling the tree-line.

Data are lacking for the monsoon-dominated summer months, but the altitude profile in September and October was broadly similar, with something of a shift upwards onto alpine meadows. This suggests that much of the time from May to October was spent above 3000 m, with birds reaching as high as 3800 m. The altitudinal distribution recorded in December and January suggests that there must have been a rather rapid retreat from the high elevations during a short time, between late October and early December, at any rate in this part of the species' range. Overall, inhabiting an altitude range of 1800-3800 m, the birds were found between 2500 m and 3400 m during the breeding season, broadly encompassing the upper part of the oak-dominated forest and the subalpine forest, the exact distributions of which depend on locality, slope and aspect.

A similar pattern of altitudinal movements through the year seems to apply to the Koklass Pheasant too, although only just over one third of the number of records were obtained. Nonetheless, a picture does emerge of several species being forced down by the winter snows, and then following the retreating snow-line upwards again in the spring. Of the pheasants in the region, only Himalayan Monals were regularly found in completely snow-covered areas, and here they appeared to survive by staying near steep, south-facing slopes which would remain under snow for only a short while after a snowfall.

Interestingly, limited information from China seems to suggest that the congeneric Chinese Monal does not descend even

Although it occupies fairly arid habitats, the Red-billed Francolin does not normally stray far from water, as it needs to drink regularly. It visits water-holes or other drinking sites in the late afternoon, when many species of birds and mammals may congregate to drink. Here three Common Grenadiers (*Uraeginthus granatina*) and one Grey-headed Sparrow (*Passer griseus*) accompany the three francolins. Note the finely barred plumage, the red bill and the yellow eye-ring, the main field characters of this species.

[*Franklinia adspersus*, Etosha National Park, Namibia.
Photo: Des & Jen Bartlett/ Survival]

slightly in the winter. The species was found at the same altitude in November and January as in summer, at around 4000 m.

Many other species living on mountain sides occupy upper zones during the summer and descend during winter, when weather conditions make life difficult or impossible at high elevations. Although there is less detailed information available on the extent of the altitudinal movements for these species it seems that some of these local migrations may be quite substantial. For example, the Himalayan Snowcock may climb 1500 m, or even as much as 3000 m, each spring to reach its summer quarters, and the Satyr Tragopan may winter as much as 2000 m below its summer altitudes.

Movements across land and water on a large scale are only seen in the *Coturnix* quails. The only member of the genus that does not appear to move much is the Brown Quail (*Coturnix ypsilophora*), which is believed not to move far from water sources. Otherwise, the genus includes species that undertake regular movements, namely the Common and Japanese Quails, or are partially migratory or nomadic, such as the Rain Quail (*Coturnix coromandelica*) and Asian Blue Quail. By and large, the routes that they follow are poorly known, and such little information that exists points towards a mosaic of complex flight patterns. The migration of the Common Quail, for example, is considered somewhat enigmatic, as it is surrounded by many unanswered questions. It typifies the complexity of the movements of these species.

Although generally reluctant to fly, once the Common Quail is airborne, its flight is swift and direct, two attributes which help it cover large distances, including sea crossings. Some of the birds that breed in Europe may remain as far north as the British Isles and Germany throughout the year, but in general most apparently winter south of the Sahara in arid steppes. Most are believed to winter from Senegal east to Sudan and Ethiopia, a few birds reaching the grasslands of Ghana and Sierra Leone, where the forest belt at the equator is considered to prevent further southward migration. Birds that breed in Africa are thought to be largely locally nomadic in Central Africa, but more regularly migratory in the south, arriving to breed in Natal and Cape Province, South Africa, during the spring months of September and October. They depart for their more northerly winter quarters in northern Namibia, Angola, southern Zaire and west-

ern Zambia in the autumn, although some birds may overwinter in the breeding range, if local conditions are favourable. The irregular movements of the birds in Central Africa may be a response to rainfall patterns, birds appearing after the onset of rains, possibly breeding and departing, but then not returning in similar abundance again for some years.

The migratory routes of the European birds into Africa are intriguing. Southward autumn passage across the Mediterranean Sea peaks in mid-September, birds moving in a broad front and flying but a few metres above the waves. The huge numbers of birds landing within 300 metres of the shore may be heavily trapped in some places, most notably in Egypt. The Sahara is then crossed without a break. Ringing recoveries suggest that there may be a circular route around the western Mediterranean. With some birds breeding around the Mediterranean, and the chance of late influxes into northern Europe, the overall picture is rather confusing. Consequently, it has been concluded that migration routes may vary from individual to individual and from year to year.

Radio-tracking has permitted the ranging behaviour of a few species to be explored. For example, the way in which male Malaysian Peacock-pheasants roam about the forest appears to be different to that of the females. Whereas males seem to be constantly on the move around a home range of up to more than 35 hectares, females stay within a much smaller area of less than 15 hectares. There does not seem to be a predictable daily pattern in which the birds wander around their home ranges, and they may be active throughout the day. Individuals can cover over 300 m in a period of two hours, which would imply that they are not foraging as they go, because the process of scratching at the litter and flicking over leaves takes time.

Predictable daily movements may be seen in many open country species, such as the Stone Partridge (*Ptilopachus pectoratus*), in which birds emerge in the morning to feed, before retiring to shady areas during the midday heat, re-emerging in the late afternoon to feed once more or to drink. Regular daily feeding movements are also reported for some species of grassy or scrubby hillsides, such as the Altai Snowcock, in which the birds fly downhill after calling, only to work their way back up the hillside, whilst feeding.

The snowcocks of the genus *Tetraogallus* are the most vegetarian members of Phasianidae.

Insects form an insignificant part of their diet, even at the chick stage, in contrast with most of the other species, for which insects are important during this early period. The grasses and herbs that grow sparsely on rocky slopes, only slightly below the snow-line, are one of the major resources of the Tibetan Snowcock. This species occurs at greater altitudes than any other member of the family, and it has been recorded at 5800 m in the western Himalayas. The white underparts, with black streaking mainly on the flanks, distinguish this species from other snowcocks.

Relationship with Man

All the families of Galliformes have been associated very closely with man for much of recorded history. This has primarily been because, as large birds, they make a protein-rich meal, should they be snared, shot or otherwise caught, and also because they lay such big, nutritious eggs. Whether considering the cracids of the New World, the francolins of Africa, the pheasants and partridges of Europe and Asia, or the megapodes of Indonesia and the South Pacific, the Galliformes are unrivalled among birds for their impact on man.

Of these groups, it is perhaps the pheasants which have had the most profound and pervasive impact on man. Their influences have been various, including taking on religious significance in many parts of Asia, providing food and sport, and even sustaining local economies in developed countries in today's world. The reason for this probably lies in the fact that a few species were hardy enough to live in close proximity to man, and even to be kept, with the result that they became intimately known. Not only would these few species stay close to human settlements, but they would also survive long journeys across land or sea. In addition, the females would produce yet more food at regular intervals in the shape of eggs! Consequently, some of these birds were well known outside their native ranges long ago, and they seem to have become important to man wherever they have been taken.

Some pheasants were well known over 3000 years ago, when they were depicted in embroideries and paintings in China and elsewhere. Ancient Greeks, like the playwright Aeschylus, knew of the Ring-necked Pheasants of Colchis, and the Indian Peafowl featured in Sanskrit writings and Greek mythology. Many pheasants, francolins and partridges have long been snared, for food, providing a varied diet for the peoples of parts of Thailand, China and the forests of south-east Asia and the Congo, amongst others. Whether or not these birds have been exploited as a food source has depended to some extent on religious beliefs. For example, the many francolins, quails and guineafowl (Numididae) present in the Horn of Africa are believed to benefit from the non-hunting beliefs of both Christians and, to a lesser extent, Muslims, and the ground-dwelling forest wildlife of Bhutan

in the east Himalayas is still rich thanks to the Buddhist tradition of that country.

Of all the birds, if not all the animals, known to man, the species which has had most impact on many varied aspects of human life is, without doubt, the Red Junglefowl. As the domestication of this species has featured so prominently in human history, it is worth exploring this association in some detail. The association arose and has flourished essentially because time and time again the domestic fowl has provided a living and reproducing source of food for seafarers and colonizers, but also because it has stirred a wide range of fears, hopes and emotions, it has been invested with religious symbolism, and it has provided sport and recreation of various kinds.

Indeed, the intimacy with which man has been associated with the domestic fowl is indicated by the influence that it has had on language the world over. In English, for example, there are many words or phrases referring to the strength, aggressiveness and strutting nature of the cock fowl. Indeed, the word "cocky" meaning impudent or cheeky is derived from the appearance that a displaying cock gives, and the word "cock" itself, meaning to place upright or rise, is again derived from the impression of swelling up or becoming taller that a cock fowl gives when beginning to display. "Cock-a-hoop", "cock-sure" and many other phrases are rooted in this expression of strutting, confidence and arrogance, with no cause for concern about daily matters. When "chicken" or "chicken-hearted" is used to mean cowardly, it refers to the impression gained long ago that young domestic fowl appear very timid and run towards the hen at the slightest hint of danger. Traditional Malay sayings, of which there are plenty making reference to chickens and other pheasants, include *seperti ayam di-makan tungau*, "like a fowl plagued with fleas", to describe someone who is sickly, and *bagai kuang memek di-puchok gunung*, "like an Argus Pheasant calling, away on a mountain top", referring to the hopeless longing of a despairing lover.

Whilst the Green Junglefowl of Java has, on occasion, been thought the ancestor of the domestic chicken, there is strong evidence to suggest that it is actually the widespread Red Junglefowl that is the progenitor of the bird that is now such an important part of human life everywhere. When and where the wild Red Junglefowl was first kept for mankind's benefit is,

During the breeding season, male Indian Peafowl establish small territories in which they perform their well known courtship display, erecting and fanning the train in front of the female. Normally, several dancing grounds of different males can be very close to one another, resulting in frequent territorial intrusions. When these occur the owner defends his territory fiercely, at first with threats, but if these do not work, through vigorous fighting.

however, less clear. The uncertainty over the date at which this first happened is summed up by W. Beebe, who wrote, "Somewhere in the far distant past, exactly when we shall never know, some primitive race of mankind captured living junglefowl and tamed them". It seems that the junglefowl was kept by the civilizations which inhabited the the Indus Valley in the third millenium BC, and India, rather than the areas further to the east in south-east Asia, is most probably the original centre of domestication. These Indian settlements were centred on two capital cities which lay along the Indus River, Harappa to the north, on the Ravi River just above its confluence with the Indus, and Mohenjo-Daro in the plains to the south. These civilizations, which were to remain unequalled in India for their civic organization until modern cities appeared, also had domesticated sheep, goats and pigs, as well as buffaloes, camels and elephants.

Piecing together what is known about the journey of the domesticated chicken through both time and space tells a revealing story about the history of mankind's travels and exploration, as chickens, once identified as a source of food, accompanied these voyages everywhere. Not long after the domestication of the fowl in the Indus Valley, it appeared in Persia and spread through Crete and Phoenicia, which is now primarily coastal Syria, to central and north-western Europe, where it had arrived by 1500 BC. Further south, the keeping of domesticated chickens spread somewhat more slowly through the western part of the Mediterranean from Greece. Domestic fowl were present in both Egypt and China by 1500-1400 BC, although they were possibly not commonly kept in the former until several centuries later.

It seems, therefore, that chickens were kept by people throughout many parts of the world by the first century AD. Red Junglefowl were already on the South Pacific islands by the time that European settlers first visited them. It is believed that early Pacific seafarers took chickens with them on voyages throughout the Micronesian, Melanesian and Polynesian islands. During these trips, which were probably undertaken mainly to colonize new islands, village chickens were kept and some of them became feral on most of the islands that were visited. They were found on the Mariana Islands at the time of Magellan's voyage in 1521 and were common in the wild on

the coral island of Tinian in the south of the Mariana chain by the time Pascoe visited it in 1742. South-east of the Marianas, domestic fowl had probably been taken to the Santa Cruz Islands, to the north of Vanuatu, by 1565, and they were noted by Quiros on the Marquesas in 1595. In the following two hundred years, explorers such as Cook, Gonzales and Bligh reported that they were already found throughout the Pacific islands. Now there are Red Junglefowl living wild on many of these islands. They were taken to the Americas by Europeans, Columbus taking these birds with him on his second voyage to the West Indies in 1493, and many tribes in South America have long raised domestic fowl.

Why have the fowl lent themselves to such close association with man? There are, perhaps, three attributes of Red Junglefowl that particularly attracted mankind to them so early. In the first and most significant instance, they provide a rich source of food, as both the flesh and eggs were found to be edible, and through breeding particularly good birds and feeding them well, man found that either large birds or those which laid many eggs could be produced. Without doubt, this was the main driving force in their domestication. Secondly, once they were domesticated it was realized that the aggressiveness of the males could provide exciting sport, and, as a result, cock-fighting has long been practised in many parts of the world. Finally, in some areas, the breeding of all manner of different types of domestic fowl has been so popular that many breeds of poultry of all shapes and sizes have been produced. Now, these birds are bred for exhibition and are exhibited in a great variety of shows.

Not only have domestic fowl been taken to more parts of the planet than virtually any other animal, but they have also entered into a great many aspects of human life, invoked as guardians of spiritual and physical well-being. Whilst continuously being exploited, they have been variously admired, feared, revered, or viewed with suspicion throughout their association with man. Al-Qazwini, a thirteenth century ad Arabic writer, for example, wrote that, "the cock is the most lustful and vainest of birds...One of the strangest things about it is that it knows the watches of the night, and apportions the times for its crowing according to the length or shortness of the night...". He goes on to say that a white cock which has a divided comb

The Ring-necked Pheasant tends to initiate its territorial activity in spring, when males start to patrol their prospective territories. Calling becomes more regular and more frequent as the season progresses and the territories begin to take shape, and soon territorial disputes between neighbouring males are rather common, as they attempt to establish the precise limits of their property. Such disputes often start with the birds facing each other and sometimes walking along together, with the neck feathers bristled up and the red wattles swollen to dramatic effect. Threat calls are made, and violent jerks of the head may follow, as may a certain amount of aggressive grass-pulling. If this is not enough to decide the quarrel, a fight can break out, the birds jumping at each other and trying to take a bite at each other's wattles, or kicking out with the claws and spurs. After a brief struggle, one of the birds usually gives in and departs, hotly pursued by his victorious opponent, but very occasionally one of the birds may be killed.

[*Phasianus colchicus*.

"Wing-whirring" is the name given to an action whereby a bird produces a whirring noise by beating its wings very fast, so as to cause vibrations. It is one of the most characteristic elements in the courtship display of male gallo-pheasants (*Lophura*), which also use it as a means of challenging other males and as a warning. In the Silver Pheasant, "Wing-whirring" by the female is also common and it has been suggested that it may be used like a contact call, for reassembling the members of a family group.

will keep the Devil away from the house in which it dwells, and that slaughtering such a bird leads to loss of wealth and suffering. Earlier than this, in about 300 bc, it was written in India that man can learn four things from a cock, namely to fight, to rise early, to eat with his family, and to protect his spouse when she is in trouble.

Many medicinal benefits have been attributed to the cock at various times in history and in various parts of the world. A drink comprising the dried and ground comb will, when taken, force all bad habits to leave a man, and the smoke given off when drying the comb will benefit a madman. More specifically, poor sight can be improved by applying to the eyes a salve made from the gall, especially if the gall is placed in a silver vessel and applied continuously. The gall was also reputed to recover memory loss, if it was mixed with mutton broth and taken in the morning on an empty stomach. Binding the wing to a fever-stricken patient cures the sufferer, and the wing will also give a rider boundless energy when attached to his loins. The blood can be beneficial or detrimental. If extracted during a cock-fight and mixed with food, those that consume it will argue amongst themselves, whereas if blood is mixed with honey and warmed on a fire, such a concoction will increase a man's virility.

The cock has also been of great religious importance throughout its association with mankind. To the Zoroastrians of ancient Persia, who were known as fire worshippers, the cock was an object of sacrifice. The Greeks dedicated the cock to three Gods: to Apollo, as it heralded the rising of the sun; to Hermes, because its crowing called men to work; and to Aesculapius, because of the virtues of retiring to sleep and rising early. In the thirteenth century, the aforementioned Islamic writer Al-Qazwini, stated that God "has created a cock beneath his throne, with wings that can extend beyond the East and the West; and towards dawn he spreads his wings and flaps them, and raises his voice in praise of him". When this cock stops crowing, the day of judgement is at hand. Believed to have been introduced to Palestine by about 200 bc, there are but one or two dubious references to the cock in the Old Testament of the Bible, whereas both the New Testament and the Talmud carry references. In the New Testament, the cock crowing at dawn was used to keep time, as when Peter denied Jesus

three times and then heard the cock crow and was filled with anguish. Traditionally the cock has been the sacrificial animal of the Jews, being an atonement offering at Yom Kippur, a man giving a cock, and a woman a hen. The cock was used to ornament Gothic churches as it was the standard of war to the Goths.

The importance of domestic poultry as a food source throughout the world is illustrated by the scale of the industry in the United Kingdom. During 1993, over 30,000,000 chicks were installed to produce eggs for consumption, about 650,000,000 chicks were destined to be reared as table birds, and in the region of 850,000,000 eggs were put into incubation to be raised as breeding and multiplying stock. These figures indicate exactly how significant a part of man's diet the descendant of the Red Junglefowl has become.

Whilst in earlier times the cock was believed to have many medicinal properties of its own, its contribution to modern medicine is as a model for scientists to try and understand some of the formative processes in the brain, such as vision, learning and memory. Rather than being of direct use to medical research, it is used for investigating basic biological questions concerning the formation and functioning of brain processes.

Domestication of the Red Junglefowl has had an impact on mankind that is impossible to overestimate, but it is not by any means the only member of this family to have had a major influence on people in different countries.

The Chinese have a very close relationship with many species of pheasant. The Brown Eared-pheasant is considered a symbol of bravery because of the battles that the males fight. Indeed, the generals of most emperors from the times of the Warring States, in 475-221 bc, to the Qing Dynasty, AD 1644-1911, placed the tail feathers of this pheasant in their helmets. The Rooster, inevitably once again referring to the descendant of the Red Junglefowl, is the only bird included among the twelve animals of the Chinese Zodiac, in which each animal represents a Chinese year in a twelve year cycle. The Rooster symbolizes the five virtues of being a good omen, authoritative, courageous, good and confident. It is a good omen because of the bearing with which it carries itself, its comb lends it authority and the spurs show its courage. It is good because it always shares its food, and finally the assurance with which it

The male Himalayan Monal is one of the most admired of all pheasants, perhaps mainly because of the metallic gloss of its brightly coloured plumage. In its courtship display, as performed by this bird, the golden orange tail is raised and spread, the purplish blue wings are lowered to such an extent that the feet and legs are completely hidden, the feathers of the mantle and neck are fluffed out, showing the beautiful metallic colours to their best advantage, and the long crest, formed by a tuft of racket-shaped feathers, is erected. The bird holds this position for a few seconds, motionless apart from slight movements of the head which make the crest shimmer and quiver.

greet the sunrise indicates its confidence. To celebrate the last year of the Rooster, 23rd January 1993 to 9th February 1994 in the Gregorian calendar, the Beijing Natural History Museum mounted an ambitious exhibition to show how important this species, and the other Galliformes, have been to man, and to highlight the plight of the Chinese species, in particular.

By and large not used by man as a staple source of food, not widely used for medicinal purposes or sport and hardly ever viewed with fear or superstition, the Indian Peafowl has mostly been admired for the beauty of the male. Reference of the Indian Peafowl does not seem to go back as far as does that of the Red Junglefowl. Although it is constantly referred to in Indian mythology and Sanskrit writings, the first mention of the bird outside India was not until the time of Solomon. His Phoenicians, voyaging to the coast of India, brought the Indian Peafowl back to the Syrian mainland, and also to the Egyptian Pharaohs.

Subsequently, the early Greeks described how the train of the peacock became covered with the eye-like ocelli. The god Argos, whose body was covered with eyes, had been told by Hera to watch Io, who had been turned into a cow, but he was killed by Hermes when carrying out this duty. Hera then took Argos's eyes and put them onto the peacock's tail. The species was not widespread in Greece until Alexander the Great brought it back from his travels in the latter part of the fourth century BC, but, according to Aristotle, it then spread rapidly. Alexander was so struck by the male's beauty that he imposed a severe penalty on anyone caught doing it harm. Referring to its calls, however, Aristotle quotes Aldrovandros, who wrote that "though he be a most beautiful bird to behold, yet the pleasure of the eyes is compensated with many ungrateful strokes upon the ears, which are often afflicted with the odious noise of his horrid cry".

In its Indian homeland, the peacock is sacred to the Hindus as it is the vehicle upon which rides the god Kartikeya, son of the Lord Shiva and Parvati, and brother of the elephant-headed god Ganesh. There is considerable folklore associated with the peafowl across the length and breadth of India. It is considered one of the main destroyers of snakes as it is able to hypnotize a snake and addle its eggs, and, in one of the few medicinal qualities accredited to peafowl, the flesh of a peafowl can be

taken to help cure a person bitten by a snake. In Sri Lanka, Singhalese medicine has used the fat as a cure for rheumatism, sprains and dislocations, and the ocelli-bearing feathers fight diseases of the eye, while the ocellus itself, when smoked, is an antidote to rat-bite.

Outside India, the fact that the peacock has been considered a bird of great beauty and magnificence has led to its symbolizing wealth and power. For example, during Roman times, a successful breeder of peafowl could make quite a living providing birds for the table of lavish feasts, at which peacock's tongue was considered a delicacy. In England in the Middle Ages, barons served up roast peacock at their banquets to prove their wealth, and the lawns of stately homes resounded to the call of the free-ranging peacocks.

As well as using the Indian Peafowl as a symbol of their wealth, members of the British aristocracy in the Middle Ages demonstrated their status by hunting other phasianids, most notably the Ring-necked Pheasant. Native to the Eastern Palearctic where it is distributed from the eastern shores of China west to the Caucasus Mountains, it is commonly called simply the Pheasant, or the Common Pheasant, in most of its introduced range, as it is the only member of the subfamily to occur in most regions outside Asia.

The Ring-necked Pheasant is alleged to have reached Europe, when Jason brought it back on the Argo after his search for the Golden Fleece. Indeed, the scientific name of the species honours the supposed locality of these birds, along the River Phasis in the land of Colchis, a region of the Caucasus, although it has also been suggested that the Romans were the first to make mention of the pheasants in this region. The Romans may have introduced pheasants to Britain, Italy, Germany and France, from where the many recipes indicate that they were avidly sought after for their exquisite taste. Within the last 300 years, the Ring-necked Pheasant has been taken to much of Europe, North America, some Australian islands and New Zealand, among other areas.

Whether the species was introduced into Britain by the Romans or much later during the Norman conquest, it was certainly established and breeding in the wild by the late fifteenth century. It was granted some degree of protection by the Royal Courts. Charles II, for example, only allowed

The courtship display of the male Bulwer's Pheasant is the most elaborate of all in the genus *Lophura*. The tail, consisting of 15-16 pairs of long, broad, curved snow white rectrices, is spread and arched high over its back, almost until it touches the neck, while the outer 6-7 pairs of rectrices are drooped down, so that their bare quills scrape the ground, producing a rustling noise as the bird moves forward. The bright sky blue face wattles in their normal state look like those of other *Lophura* species, but now they are greatly distended and stiffened, forming a ribbon-like, curved band about 18 cm long, broken only by the crimson eye, which stands out all the more because of the eye-ring of the same colour.

[*Lophura bulweri*.
Photo: Kenneth W. Fink]

the richest 5% of landowners to hunt anything at all, and imposed quite harsh penalties on lawbreakers. Needless to say, these rights were earnestly sought after and, if obtained, jealously guarded.

For many years after the establishment of the pheasant as a gamebird, the prestige, by implication of wealth, associated with shooting meant that the habitat in which the pheasant thrives was protected. Indeed, it has been suggested that the popularity of a day's pheasant shooting has played a major role in the preservation of lowland woodlands in southern England. This is because large estates, under ever-increasing pressure to make every acre of land pay, would have turned over all the land to agriculture of one sort or another, if the pheasant habitat had not been able more or less to pay its way. These pressures may well have been greatest, when, after the rationing imposed because of food shortages during the Second World War, the British Government sought to make the country self-sufficient.

The money spent on managing British Ring-necked Pheasants now reflects their importance to some rural economies. This species was the subject of a very large part of the staggering £400,000,000 that is estimated to have been spent on game shooting in 1981. At present, this is equivalent to somewhere in the region of ten times the amount of money that the British Government's conservation department has to spend on all of its activities in a year. It seems quite remarkable that ensuring that a single species of pheasant is alive and well can be so important to the economy of an industrialized country.

The Grey Partridge has also been shot in Europe since the Middle Ages. Inhabiting open landscapes, it now depends largely upon sympathetic farm management of areas dominated by fields of cereals. The drive towards intensification of farming practice has caused a marked decline in numbers of this species throughout its range.

The amount of research that has been conducted on these "game" species gives a good indication of the amount of money spent on game shooting. Both the Ring-necked Pheasant and the Grey Partridge have, for many years, been the subjects of various management-related research projects, and are the subjects of authoritative books written recently, largely summarizing the work undertaken by The Game Conservancy

Trust in Britain. The Grey Partridge has one of the longest research pedigrees of any bird anywhere, having been the subject of intensive research since 1930, perhaps surpassed only by the Red Grouse (*Lagopus lagopus scoticus*), on which research began in 1905.

The aim of much of this research has been, and still is, to understand the processes that govern the species' lives and influence their numbers by affecting reproductive success, recruitment and survival. Ultimately, this research aims to propose how the habitat of these species can be managed to increase the numbers of birds surviving. Research programmes are increasingly designed to reconcile the demands of ever more economically orientated land managers, and the conservation requirements of both species and habitats.

The Mountain Peacock-pheasant is one of the latest species to have been successfully reared in captivity for the first time. It was almost unknown in collections until the end of the 1970's, but breeding success in Hong Kong and Malaysia has led to the establishment of a small population, which was estimated to number 111 birds in 1993. In its lateral display, the male walks daintily around the hen, offering a frontal view of its broad, graduated tail, which is decorated with numerous metallic green patches.

[*Polyplectron inopinatum*.
Photo: Kenneth W. Fink]

Of all the varied types of head adornment worn by the males of most pheasant species, the lappets exhibited by the tragopans in their courtship displays are amongst the most peculiar. The elaborate pattern of the lappet varies from species to species, and one of the largest lappets, that of Temminck's Tragopan, is dark blue in the centre spotted pale blue, with eight scarlet markings down each side.

Normally, the lappet is completely retracted and remains practically invisible, but during display it is suddenly expanded down over the breast, forming a bright, bib-like flap that is exposed in front of the female. At the same time, the male adopts an upright position, with its wings lowered and half spread. At the climax of the display, the bird dramatically erects two small, fleshy blue horns, which in normal condition are shrunk and concealed beneath the crown feathers. After a few seconds, both the lappet and the horns are quickly deflated and the bird resumes its normal aspect.

[*Tragopan temminckii*.

Photos: Kenneth W. Fink]

Treating a bird species as a crop to be harvested is somewhat controversial, although there is always the argument that the money spent on shooting pheasants has saved much of the ancient oak and beech woodland, at any rate in England. On a global scale, harnessing this interest in hunting wild species may offer long-term survival prospects for a number of species and their habitats. The rationale is that if there is sufficient interest in hunting for sport, then sustainable practices can be adopted so that both the habitat and the hunted species are conserved to allow hunting to take place. The income generated by shooting should then provide money badly needed for conservation. It is an emotive issue, however, and some Galliformes are likely to be considered ideal for this practice, because of their size, ground-dwelling nature and palatability.

In Zimbabwe, for example, hunting of gamebirds has not required a licence since the Parks and Wild Life Act was passed in 1975. Recently, management recommendations have been made that should ensure that hunting of the country's terrestrial birds is sustainable. The species concerned include seven francolins, especially Swainson's Francolin, and the Harlequin Quail; the recommendations are currently being tested.

In South Africa, the hunting of species, other than those traditionally regarded as "Big Game", is becoming very popular. In the eastern part of Cape Province, on the Stromberg Plateau, hunting of the Grey-winged Francolin has become a commercial proposition over the last ten years. Other species which are shot, though rather less systematically, include Swainson's Francolin, the Crested Francolin (*Francolinus sephaena*) and the Natal Francolin (*Francolinus natalensis*). The formation of the African Gamebird Research, Education and Development Trust, known as AGRED, is the result of those interested in hunting in South Africa joining together in an undertaking to ensure that gamebird populations are sustainably managed in the country. The 2,000,000 Rand, or so, that this young industry is now generating for cash-starved rural areas each year may point the way towards conservation that is economically viable.

This concept of sustainably harvesting species has been termed "Wise Use". The essence of this approach is to try to ensure that there is an economic incentive to conserving species and their habitats. Two examples may illustrate this. It seems that, at any rate in much of its range, Grey Partridge numbers

The fantastic courtship dance performed by the male Great Argus is one of the wonders of the bird world. The display begins when a female enters the arena, a patch up to five metres wide which has been cleared by the male. At first, the male circles round the female ceremoniously, coming closer and closer, until he suddenly thrusts his wings wide open and inverts them, with the primaries spread forwards touching the ground, the inner secondaries meeting at the top, and the entire expanse of the wings curving upwards and around to form a huge funnel, in which the ocelli of the secondaries are prominently exposed. At the same time, keeping his head and neck hidden from view, the male waggles his tail back and forth and vibrates his plumage so as to produce a rustling sound.

[*Argusianus argus argus*.
Photo: Kenneth W. Fink]

A number of specialized displays can precede copulation in the Ring-necked Pheasant, amongst which the most important are probably "Lateral-displays", with the male strutting round the female, spreading his tail and drooping a wing towards her, and "Tidbitting", which involves calling and offering food to her. If receptive, the female will squat, inviting the male to mount her, and copulation follows. In the latter part of the breeding season, copulation often takes the form of "rape", as the male forces himself upon the female, grasping her nape feathers with his bill; males that do not hold territories are probably able to copulate only by means of rape. In the moments surrounding copulation, the male's red face wattle and ear tufts are noticeably swollen.

are highest where the economic incentive is enough to justify the cost of habitat management. Similarly, in Zimbabwe, it has been seen that if local people are assured of meat and money, they are prepared to look after wild species for sport hunting. This general approach has now been accepted as having the potential to show the way forward for the conservation of some species that are closely linked with man. Typically, these are species that are exploited in various ways, whether it be on a small scale or at a massive, unsustainable level, and many phasianids, as well as other Galliformes, are subject to these direct forms of human exploitation. Promoting such wise use of animal and plant species is the remit of the Specialist Group on the Sustainable Use of Wild Species, which operates under the auspices of IUCN's Species Survival Commission.

In addition to the importance of phasianids as gamebirds, some species have also been amongst the most typical ornamental birds, due to their spectacular beauty (see Morphological Aspects). In addition to the esteem bestowed upon the Indian Peafowl, there are many other species which have long attracted man through their striking appearance. It is the pheasants more than the partridges, quails, francolin and snowcocks that have captured the imagination, undoubtedly because the pheasants are larger and, in general, more colourfully adorned than most perdicines. Ornamental pheasants have been sought so that they may be exhibited in both public zoos and private aviaries, or to wander freely across the lawns of large houses, as vivid adornments. The extravagant plumes of some species are of cultural importance in several areas. For example, the magnificent tail feathers of Reeves's Pheasant, which may reach 150 cm in length, have traditionally been used to adorn headdresses in Peking Opera. Nowadays, plastic imitations are used, which is a blessing for a species that is very reduced in numbers in the wild, and is now found in fragmented populations. Similarly, the train feathers of the Green Peafowl are used in Javanese dances.

The leisurely appreciation of these fine birds appears to have been of Western European origin, as the aristocrats of several countries employed collectors and dealers to bring back

examples of the many dazzling animals that were to be found in countries which at the time made up the empires of the European powers. The aristocrats who maintained collections during the late nineteenth century in Paris and London were continually sent new pheasants. Indeed, the 1860's and 1870's must have been especially exciting times, as many species new to science were dispatched live to Europe to be paraded before the public, and widely admired.

Apart from the Red Junglefowl, Ring-necked Pheasant and Indian Peafowl, the first pheasant recorded alive in Europe was probably the Golden Pheasant, kept as early as 1740, when Albin reported in his *Natural History of Birds* that several were in the collections of "our nobility and some curious gentlemen". The Grey Peacock-pheasant soon followed, judging by the paintings made of pheasants present in Mr John Munro's collection in London during 1745. Subsequently, Reeves's Pheasant was kept in Macao, China, by an Englishman by the name of Beale in 1808. Reeves himself bringing one of the cocks to Europe in 1831 and describing the species. The Green Peafowl appeared in aviaries in Cape Town, South Africa, in 1813, sent from Macao, and reached Europe in 1831, by which time Lady Amherst's Pheasant had also arrived. This last species only survived for a short time in London Zoo, having been kept in India for two years prior to shipment to England. In the mid-1920's the King of Ava presented two males from the mountains of Cochin-China to Sir Archibald Campbell, who passed them on to the Countess Amherst.

These occasional importations were nothing compared to the influx of new species that took place during the second half of the nineteenth century. In 1872, D. G. Elliot prepared the first monograph of the pheasants, a work which contained some exquisite hand-coloured reproductions of watercolours painted by J. Wolf. Although not all the pheasant species had been described when this work was published, privately, by Elliot himself, it is a marvellous celebration of the beauty by which this group of birds has entranced man.

The keeping of pheasants, and to a lesser extent partridges, quails, francolins and snowcocks, has become

The nest of the Red-legged Partridge is a simple scrape on the ground lined with some plant material, usually sheltered by grass tussocks or a bush. The nest is constructed by the male, and he will sometimes make more than one, at different sites, for the female to choose from. The eggs, normally 10-16, are cream-coloured, finely spotted reddish brown. Incubation lasts 23-24 days and is carried out by the female alone, although the male will sometimes sit on the nest at an early stage when there are still only one or two eggs. The female sometimes lays a second clutch in another nest a few days after finishing the first, in which case this second clutch is incubated simultaneously by the male alone.

[*Alectoris rufa*.

increasingly widespread since those early days, when it was the exclusive preserve of wealthy naturalists and the like. Virtually all species of pheasants, and many perdicines, are now maintained in captivity in many countries. The appeal of this family to such a great number of people has resulted in many species being widely bred. Indeed, there are far greater numbers of most of these species in the collections of private aviculturalists than there are kept publicly, in zoos and bird gardens. Whilst it is increasingly realized that these captive collections must be properly managed if they are to contribute to the long-term conservation of the members of this family in the wild, most private aviculturalists began to keep these birds simply because of their beauty and some of their habits.

Being able regularly to see and appreciate such beauty and elegance appeals to the sense of the aesthetic; it is an aspect of man's relationship with the family that is impossible to quantify, but in some ways it is as important to man as the chicken's flesh. The struggle for conservationists is to ensure that these birds survive for the future, a considerable task (see Status and Conservation).

Status and Conservation

Many species of pheasant, partridge, quail, francolin and snowcock are believed to be threatened with extinction. In some cases, such as that of the Himalayan Quail (*Ophrysia superciliosa*) and Edwards's Pheasant, this may be mean that extinction in the wild has recently taken place, but has yet to be proved. At the other end of the scale, it may indicate that widespread and numerous species are almost certainly suffering such a rate of population decline that there is a chance that they will become extinct during the next 100 years. An example of the latter case is that of the Great Argus, a large-bodied inhabitant of lowland tropical rain forest in the Malay Peninsula, Sumatra and Borneo. This habitat was once distributed continuously throughout the region, but its loss to logging, and land clearance for other reasons, has probably caused a sharp decrease in the numbers of this species, and of other sedentary lowland forest specialists, over a relatively short period of time.

A continued decline in the population at the current rate is sufficient reason to be concerned for the long-term survival of the Great Argus.

Because so many of the species in this family are very poorly known, particular efforts have recently been made to collect information on their current status and conservation needs, so that the extent of any threats to their survival can be assessed. This onerous task was undertaken by the World Pheasant Association, and centred on a Conservation Assessment Workshop held at Antwerp Zoo in February 1993, a meeting co-organized by BirdLife International and the Captive Breeding Specialist Group of IUCN's Species Survival Commission, in addition to WPA. This is the first time that data on all phasianid species have been sought out and gathered together, to allow the systematic appraisal of whether or not a species is threatened, and, if it is, how immediate that threat may be. Other families included were the Odontophoridae, the Numididae and the Megapodiidae.

Many previous considerations of the status of birds have been based on a starting point that a species is known to be facing problems, with the result that those species that are not subject to obvious pressures are easily overlooked. In order to avoid this pitfall, the Conservation Assessment of the phasianids considered all species, whether traditionally thought to be at risk, such as the Western Tragopan, or not, as with many of the African francolins.

An important product of the workshop was the assignment of a Mace-Lande threat category to all species, and distinctive subspecies or subspecies clusters (see page 19). These threat categories are an attempt to improve upon the subjective nature of the existing IUCN threat categories, and are still being refined. In some cases morphologically distinct and geographically isolated subspecies, or subspecies clusters, were treated separately and assigned a threat category accordingly. For example, the Silver Pheasant, while thought to be safe from extinction, contains several subspecies which are believed very much at risk, such as the race *engelbachi* from the Bolovens Plateau in southern Laos, and the Hainan endemic *whiteheadi*, both of which are endangered. In all, the 155 species in Phasianidae were treated as 181 distinct taxa, made up of 69 pheasants and 112 partridges, quails, francolins and snowcocks.

Grassland and cereal crops are amongst the habitats most commonly used by the Stubble Quail, and, as they provide both food and adequate cover, they are also suitable areas for nesting in. The nest is a scrape in the ground which the female digs with her feet; it is lined with dry grass or loose bits taken from the surrounding vegetation. The female also takes on the task of incubation, which begins only once her full clutch, usually numbering 7-8 eggs, has been laid. This is important in order to ensure that the precocial, nidifugous chicks hatch synchronously. Note the thin dark moustachial stripe of the female, a feature absent in males of this species.

ANT/NHPA]

All subsequent reference to status in this section refers to the Mace-Lande category.

There were three important outcomes of this exercise: the parts of the family's range that contain most threatened taxa were revealed; the nature of the threats facing these birds were identified; and, thirdly, a much clearer indication of the species' conservation needs and priorities emerged. Plans for conservation action have been based upon these results.

A glance at the distribution of the threatened taxa, both within their respective subfamilies and geographically, is revealing. One pheasant taxon may be extinct, two are critically threatened, 18 may be endangered, and a further 24 vulnerable. There is insufficient information available to determine the status of five taxa, and 20, a mere 29%, are considered to be safe from extinction. The *Perdicinae* are, as a whole, in better shape, although again one taxon may be extinct. Two taxa are critically threatened, nine endangered and 20 vulnerable. Five taxa are too poorly known to permit any assessment of their status, and 75, representing 67%, are relatively safe at present.

The higher proportion of *perdicines* that are safe from extinction when compared with the pheasants appears attributable to their respective patterns of distribution. The pheasants are almost exclusively Asian in distribution, containing many forest-dwelling species, especially in the tropical forests of south-east Asia. In contrast, a higher percentage of *perdicines* occurs found in the open areas of Africa and the Palearctic, and these species are often tolerant of some forms of habitat alteration, inhabiting overgrown cultivation, or even moving into fields and plantations in some instances. Many of these open country species have far more extensive distributions, often occupying more than half a million square kilometres. In contrast, the forest-bound taxa, particularly in the tropics, appear to have very specific habitat requirements, and have much smaller ranges as a result. Indeed, many forest-dwelling phasianids are considered Restricted Range Species by BirdLife International, as they have ranges of under 50,000 square kilometres. In support of this, of all Phasianidae, *Numididae* and *Megapodiidae* considered at the Antwerp meeting, 80% of the African taxa are thought to be safe from extinction, whereas in the Indian Subcontinent the figure is 52%, in China 48%, and in south-east Asia 40%. Thus the threats facing the family are

greatest in the forests of south-east Asia, the Himalayas and China, with the larger-bodied pheasants at greatest risk.

The proportion of species in Phasianidae that are threatened as a result of man's activities is amongst the highest in any bird family, and the Galliformes are among the most threatened of orders, in terms of proportion of species threatened. Part of the reason for this is the close relationship that man has had with the phasianids. Whilst the three species which are most celebrated for their association with man, the Red Junglefowl, the Ring-necked Pheasant and the Indian Peafowl, are not globally at risk, many other species are under pressure directly as a result of man's attentions. While the Red Junglefowl in its domesticated form feeds millions of people throughout the world, many other pheasants and partridges are hunted for food in the wild.

In the past, hunting probably created few problems in terms of the long-term survival of species, as human numbers were small and there were large tracts of wilderness, including forests, wet grasslands and the like. With increasing human populations, shrinking wild areas with ever better access for hunters, as well as new, improved methods for obtaining food,

The chicks of the Palawan Peacock-pheasant are cared for by the female and are regularly brooded while they are small. Chicks often take shelter beneath the female's wing, so that only their heads stick out. It is also common for chicks of peacock-pheasants to take shelter under the female's tail, even on their first day.

[*Polyplectron emphanum*,

Hoyo/Lynx]

such as shotguns and nylon snares, some species appear to have suffered considerably. For example, during his travels, C. Cordier found that the Congo Peafowl had disappeared within a radius of up to 25 kilometres from each village, track and road in the equatorial forest of Zaire.

Countries in which the hunting of ground-dwelling birds poses problems include Thailand and China. In Thailand, trapping for food has been considered one of the most serious threats for most of the phasianids in the country, such as the Long-billed Partridge (*Rhizothera longirostris*), the Chestnut-headed Hill-partridge (*Arborophila cambodiana*), Humes's Pheasant (*Symaticus humiae*) and the Great Argus. An additional problem in Thailand is that many of these species are eagerly sought after by those collecting for the bird trade.

In China, all phasianids, except the Ring-necked Pheasant, are protected by law, either as a "First Class Protected Species", the taking from the wild of which requires a permit from the central Ministry of Forestry in Beijing, or as a "Second Class Protected Species", for which a hunter requires a permit from a provincial forest department. Despite this, illegal hunting does take place, especially in remote regions, of species such as the Himalayan Snowcock and the Daurian Partridge (*Perdix dauurica*). Both of these species are considered safe from extinction at present, but the scale of exploitation is sufficient to have caused declines in some areas. The demand for traditional medicines derived from the Himalayan Snowcock, which are believed to ease rheumatic pains and a variety of other ailments, is a cause for concern. In the eastern Tien Shan Mountains, the local Kazakh hunters have traditionally been careful to take birds on a sustainable basis. But an increase in the demand for the medicines has resulted in outsiders coming into the region, and, lured by the high prices offered for the birds, they will take them at any time of the year. Indiscriminate killing of breeding birds can only have one consequence for the population, and, if local extinction is to be avoided, this unsustainable activity must be controlled.

Across the family as a whole, however, direct overexploitation of this sort poses nowhere near the same degree of threat as does habitat loss. Whether it be the clear-felling of forest for timber, the conversion of forests or grasslands to agricultural land, the drive to "reclaim" land to satisfy the need for ever-

expanding urban centres, or any other form of habitat disruption and modification, loss of habitat is the major problem facing the Phasianidae. In the wet grasslands of the *terai* belt which stretches along the Indo-Nepal border and eastwards into Assam, the Swamp Francolin is steadily losing habitat to agricultural land. In the west of its range, the marshes, and the damp reedbeds associated with them, are drained to make the land suitable for plantations of sugar cane, an important cash crop in much of the western part of this belt. In the east, it is pulses and wheat which are sown in the areas of drained land. Road building also accounts for much swamp land.

The loss of forest in the front ranges of the Himalayas and also in the tropics has, in both cases, been on a scale that has caused concern for some time. The deterioration of Nepal's forests shows no sign of lessening, with loss of forest cover caused by the extraction of branches for fuel, the lopping of oaks to provide animal fodder, and widespread grazing by domestic stock in the forest understorey. In 1979, it was estimated that as much as 60% of the country's forested land had less than 40% tree cover. Forest Galliformes in Nepal include the Satyr Tragopan, the Koklass Pheasant and the Himalayan Monal, the first of which is a threatened species, whilst the second two are not considered threatened perhaps simply because of their large ranges. Nonetheless, the rate of habitat loss, and the deterioration caused by overgrazing of the many large flocks of sheep and goats, are major worries, as they operate throughout much of the front ranges. Bhutan, in the eastern Himalaya, is the single known exception, where forest cover is still extensive and a source of national pride.

The plight of China's forest Galliformes is highlighted by the Brown Eared-pheasant, an inhabitant of montane broad-leaved and coniferous forests in north-east China. Occurring mainly in the Luliang Mountains, but also in the Dongling Mountains and on Xiaowutai Mountain, it is now split up into many small populations. The forests in which the species lives have been heavily exploited, presumably because of their proximity to Beijing, which has long been China's capital. The creation of four reserves specifically designed to protect the habitat of this species may have saved it in the short term, but the complete isolation of such small populations may have serious long-term consequences for the viability of the species.

Immediately after hatching, the nidifugous chicks of the Himalayan Monal are able to move about and to feed themselves, as is the case of other phasianids. Having performed the entire business of incubation alone, the female now accompanies her brood, normally of 3-5 chicks, to suitable places where they can find food, especially insects, as these make up the greater part of their diet in the first weeks of life. Should danger approach, the female begins to make loud, whistling alarm calls, sometimes for several minutes, while the chicks remain hidden.

[*Lophophorus impejanus*, Sagarmatha National Park, Nepal.
Photo: Joanna Van Gruisen/Ardea]

The Copper Pheasant is one of the gamebirds that is most avidly hunted in Japan. In the past, as many as almost 1,000,000 birds of either sex were shot every year. Such overhunting caused a serious decline in this species, which, in turn, led to the shooting of females being banned in 1976.

[*Symaticus soemmerringii* scintillans.
Photo: Jean Howman]

Nowhere has the destruction of forests in recent times been more complete and systematic than in the tropics. The loss of rain forest, particularly in the Sunda Subregion of south-east Asia, from Peninsular Thailand to Borneo and Java, is the result of the highly intensive extraction of timber. Although the Crested Wood-partridge is not the most seriously threatened of the species inhabiting the lowland forest of this subregion, its plight illustrates well that facing all the lowland forest Galliformes of south-east Asia. The species was continuously distributed throughout lowland rain forest from the Isthmus of Kra south through the Malay Peninsula to Sumatra and Borneo at the time that H. Robinson, C. B. Kloss and the other early twentieth century naturalists made their collections and inventories. Today, however, loss of habitat is so widespread that the Crested Wood-partridge may be endangered in Peninsular Thailand. Whilst it may still be common in Indonesia, the paucity of recent records is sufficient for its status to have been considered indeterminate in the country recently, and indeed, there are no breeding records at all for Sumatra; it may have become extinct on the islands of Bangka and Belitung, off Sumatra. In Peninsular Malaysia, it was reported as still common in the early 1980's, at the time when it was predicted that all forest below the hillfoot boundary would be logged by 1990! Thus, it seems that it may well be confined to protected areas within its range in the not too distant future, a gloomy prospect which faces almost all lowland forest specialists.

The open country species of the Western Palearctic and Africa are, by and large, not subject to the pressures that their relatives further east face. This is partly because their habitat requirements do not appear to be as narrow as those of their forest-dwelling relatives, for they can occupy a range of open habitats, such as savanna, scrub and lightly wooded grasslands, or, in other cases, arid scrub, desert or boulder-strewn wadis. Although many of these species have wide distributions, there are some instances where habitat modification has been so extensive that populations are under threat. For example, the Grey Partridge, a species with which man has had a close association (see Relationship with Man) is declining throughout much of its range, as a result of the intensification of agriculture that has taken place in Europe this century. Since the 1940's numbers of birds have declined markedly in many areas, perhaps even in all 31 countries in which the species is found (including introductions). Many agricultural areas have become so intensively farmed that an increasing portion of the original range is becoming uninhabitable for the partridge. In this case, the evidence points to the cause being intensification, such as increasing use of pesticides to boost cereal crop yields. The pesticides reduce the amount of insect life available in field margins to a level at which it can not support many chicks at all during this crucial stage in their lives. Thus, although the Grey Partridge is still considered safe from extinction, it is clear that in many areas it is struggling to survive, and that attempts to understand the problems on a global scale and halt the decline, should continue.

The numbers of most species in the family are currently declining, but some species are much closer to extinction than others, and it is clearly these species that require the most urgent attention. For one, possibly two, species, it is already too late, and another may be on the brink of extinction.

One quail is known to have become extinct through man's activities, and a second may well have gone the same way. The New Zealand Quail was last recorded in 1875, although nobody really knows the reasons for its decline and extinction; two of the most likely causes are disease, brought in by introduced birds, and predation by introduced mammals, such as stoats. From the front ranges of the central Himalayas in India, the Himalayan Quail is known only from nine specimens collected during a few years over a century ago. Taken from the slopes above the hill stations of Mussoorie and Naini Tal in Uttar Pradesh, there have been no confirmed reports since 1876. Although it is often considered extinct, all authors have appeared reluctant to consign it to history, holding out some hope that it may still survive. There are some causes for optimism, such as several unsubstantiated reports during the second half

of the present century, although the reliability of the information is uncertain.

Edwards's Pheasant poses a distinct problem for conservationists, not only because of the urgent need for conservation action, but also because in discussing this form, taxonomists and conservationists are regularly talking at cross purposes. The recently found form *hainhensis*, the Vietnamese or Vo Quy's Pheasant, has been accepted as a full species by some authors, although the limited information available indicates that it is probably better considered a race of Edwards's Pheasant. Each form has been assigned a Mace-Landé threat category, Edwards's Pheasant considered critically threatened, with the increasing possibility that it is, in fact, extinct, and the Vietnamese Pheasant believed to be critical. Several surveys by a team from BirdLife International and the Hanoi University Forest Bird Working Group since the late 1980's have failed to find Edwards's Pheasant in its historical range, where it is only known from a few localities. The Vietnamese Pheasant, in contrast, was confirmed to survive, although habitat loss and trapping for food are serious threats. Whether these two forms are, in fact, one species or two, it is clear that the Vietnamese members of *Lophura*, also including the Imperial Pheasant, are in real trouble.

The Bornean Peacock-pheasant is one of the most enigmatic Galliformes in Asia. Described in 1877 by Brüggeman, and named in honour of Herr Schleiermacher of the Grand Duke's Hessian Museum in Darmstadt, Germany, it was frequently the cause of much activity throughout Borneo by those keen to procure specimens or add the birds to their captive collections. Despite many searches, only a handful of specimens are known in museums and very few birds have reached Western collections. Today there is no clear picture of the range or habitat requirements of the species, as an incomplete record of collecting localities is all the information that exists well over a century after its discovery.

The few confirmed localities are very patchily spread in the east and south of the island, although unconfirmed reports suggest that the species may occur throughout Borneo. What is intriguing, however, is the number of searches, both specifically for this bird previously, and recent, more general avifaunal surveys that have failed to find any evidence of its existence. The rate at which forest continues to be felled on the island is extremely worrying, given the complete lack of any positive information regarding the species. Forest loss is especially severe along the major river systems, and there is a chance that these lowland forests are the main habitat of the Bornean Peacock-pheasant, as in the case of the closely related Malaysian Peacock-pheasant across the South China Sea.

The only perdicine, other than the Himalayan Quail, which may be critically threatened under the Mace-Landé criteria, is

Not all of man's alterations to natural habitats are detrimental to all phasianids. Philby's Partridge, for example, a species essentially of barren rocky hillsides in the mountains of south-western Arabia, often frequents areas of highland cultivation, and the seeds and shoots of cultivated cereals now make up a significant part of its diet. The uniform black face and throat distinguish this species from all other *Alectoris* partridges.

[*Alectoris philbyi*, Saudi Arabia.
Photo: Xavier Eichaker/Bios]

the Sichuan Hill-partridge. Endemic to the subtropical ever-green forest of southern China, it is restricted to an area which may be as small as 1000 square kilometres, while the extent of suitable habitat within this area is possibly much less. Probably always fairly limited in distribution, the species is now threatened by loss of habitat on two fronts, conversion of some forests to forestry farms, and road building leading to increased human incursions. The forestry farm activities involve clearing primary forest and replanting with a mixture of two fir species, one native to south-west China, the other not. The Sichuan Hill-partridge may still survive in the plantations that replace the natural forest, but whether the densely planted firs can support a sustainable population in the long term is another issue entirely. It is still reported to be common in forest on hillsides that are not close to the roadheads. These forests are largely untouched and the lack of roads is the best protection that the species has. Current research efforts are designed to understand the distribution of the partridge and its use of habitat in man-affected areas.

Percidine species that are considered endangered are the Djibouti Francolin (*Francolinus ochropectus*), the Manipur Bush-Quail (*Perdica manipurensis*), and the Orange-necked, Collared Hainan and Annam Hill-partridges. Subspecies considered in need of separate attention that fall into this category are the isolated Moroccan race *ayasha* of the widespread Double-spurred Francolin, and all three races of the Chestnut-necklaced Hill-partridge, although the validity of the Sumatran race *atjenensis* is doubtful.

The future of the Djibouti Francolin, endemic to an area of less than 100 square kilometres in the Horn of Africa was fully revealed in the mid-1980's, when G. and H. Welch undertook an expedition to the species' remaining habitat. They considered that slow, natural dessication of the habitat might be exacerbated by human interference to the point that this francolin might not survive into the next century. About 3500 hectares of suitable juniper forest is estimated to exist in two patches within the Forêt du Day National Park. Continuing civil unrest currently prevents any conservation initiative, action which is necessary to save the species from extinction.

Of equal concern are those species for which it is not possible to assign a threat category because of the lack of

information, and especially worrying is the plight of the Grey-striped Francolin from war-torn Angola in south-west Africa. This species is known to have been hunted, at any rate in the past, and perhaps also at present, and it may survive only in a few hectares of forest. Nahan's Francolin and Schlegel's Francolin (*Francolinus schlegelii*) are similarly little known, as are Verreaux's Monal-partridge (*Tetraophasis obscurus*), Szechenyi's Monal-partridge (*Tetraophasis szechenyii*) and the See-see Partridge. The last three have large distributions in areas that are not heavily populated by humans and in terrain that is not attractive for

The discovery of the Congo Peafowl caused a major stir in the ornithological world in the 1930's. The fact that it was placed in a new genus was important, but even more significant was the very existence of a pheasant in Africa, since all the other pheasants are restricted to Asia, barely reaching the extreme eastern fringe of Europe. The current status in the wild of the Congo Peafowl is virtually unknown, and there have been no records at all since 1982. Birds are kept in captivity in several collections, but the species is apparently rather difficult to breed.

[*Afropavo congensis*.

The race *hatinhensis* of Edwards's Pheasant was described as recently as 1975, and was classed as a full species. From the first it has been seriously threatened, mainly due to destruction of its habitat. The nominate race seems to be even worse off, and may now be extinct in the wild. The white central tail feathers are diagnostic of *hatinhensis*.

[*Lophura edwardsi*
hatinhensis.

Photo: R. Seitre/Bios]

agricultural or other uses, and, therefore, are probably not threatened to any great degree.

Among the pheasants, endangered or potentially endangered species are Sclater's Monal (*Lophophorus sclateri*) from the eastern end of the Himalayas; the Imperial Pheasant, the third seriously threatened *Lophura* form from Vietnam; the Brown Eared-pheasant and Reeves's Pheasant from northern China; and the Palawan Peacock-pheasant from the Philippines.

Both of the endangered Chinese pheasants, the Brown Eared-pheasant and Reeves's Pheasant, are receiving conservation attention from Chinese ornithologists and officials. Two reserves have been created specifically for each of these species, Panquanggou and Xiaowutai National Nature Reserves in Shaanxi Province for the Brown Eared-pheasant, and Dong Zhai Nature Reserve in Henan, and Tuoda Forest Nature Reserve in Guizhou for Reeves's. The last of these was notified in May 1992, as a result of the study by Wu Zhi-kang, who identified the area and its potential for protection.

The Green Peafowl is also in trouble, whether considered as a whole, or if each of its three subspecies is treated sep-

arately. Once widespread from north-east India and China south to Java, it has been eliminated from most of its range, partly through habitat destruction, but also because it was commonly shot by hunters until it was on the verge of extinction in many areas. The species became extinct in Peninsular Malaysia some time between 1960 and 1965, and there is no recent information from north-east India and Burma west of the River Irrawaddy where the race *spicifer* occurs. Several sites for the species have been reported from southern China, but the alleged occurrence in Tibet needs confirmation. Further south, only one site in Thailand has been confirmed, the Hua Kha Kaeng Wildlife Sanctuary, close to the Burmese border, which is the most extensive tract of unspoilt, prime riverine habitat in the country; it has been proposed as a World Heritage Site. Few localities are confirmed in Vietnam. Again, although nearly 20 sites were discovered during a recent survey on Java, many are very small and the populations within the national parks at each end of the island, Ujung Kulon in the west and Baluran in the east, are likely to remain most important for the species.

Many more pheasant subspecies have been considered worthy of separate treatment in conservation terms than have those of partridges, quails, francolins and snowcocks. This may be partly because they are, relatively speaking, better known, and distributions and taxonomic limits are, in general, somewhat more clearly defined. Subspecies classified as endangered include the nominate race of Blyth's Tragopan, while its eastern race, occurring in Bhutan, is regarded as insufficiently known; also, the geographically isolated races *annamensis*, *engelbachi* and *whiteheadi* of the Silver Pheasant, and the race *nigrescens* of the Crested Argus from the Malay Peninsula, which is restricted to several mountain tops in the Taman Negara National Park.

Whilst the recent Conservation Assessment represents the first time that each species has been considered systematically and the scale of threat facing it assessed, much work towards the conservation of this family had already been undertaken over the last 20 years, and this provided a good deal of the information used to determine status and assign threat ca-

Although the beautiful Palawan Peacock-pheasant is classified as Vulnerable according to the traditional IUCN criteria, application of the more recent Mace-Lande threat categories has led to its listing as Endangered. Endemic to the island of Palawan, its alarming situation seems to be the result of factors similar to those that affect most of the threatened species in the family: deforestation, which is particularly severe in the flat lowlands of Palawan; and hunting, both for food and for the bird trade. Undoubtedly the most emblematic of the island's endemics, this species could be an excellent flagship in conservation campaigns aimed at increasing public awareness.

The Brown Eared-pheasant is another of the many threatened species in this family. Endemic to the north-east of China, it suffered a major decline historically, due to the widespread deforestation of the mountains within its range. Nowadays, the species is only known to survive at six sites, which are totally isolated from each other. On the positive side, four of these small populations are in protected areas, and censuses carried out in 1989 in two of them, Luyashan and Pangquangou Nature Reserves, were heartening, giving figures of 2790 and 1230 birds respectively, significantly higher totals than estimates made in the early 1980's.

tegies. A major stimulus for many surveys and other initiatives has been the World Pheasant Association (WPA). Founded in 1975 to promote the conservation of the world's Galliformes, and thus taking in the grouse, turkeys, cracids, guineafowl and megapodes, much of WPA's early attention was directed towards pheasants and, to some degree, aviculture, as a means of promoting their survival.

Major conservation initiatives undertaken during that period include detailed survey work on two species then considered to be among the most threatened, the Cheer Pheasant and the Western Tragopan. Both occur in the western Himalayas, the Cheer on mid-altitude grassy slopes with scattered rocky outcrops, interspersed with pine trees and gullies, and the tragopan restricted to moist temperate forest. Results obtained during the Himachal Wildlife Project (see Movements) led to the valleys to the south-east of Kulu being proposed as the site for the Great Himalayan National Park.

Subsequent conservation efforts have taken the form of the ambitious Himalayan Jungle Project, led by BirdLife International, which has the objective of conserving an extensive tract of pristine forest in the Palas Valley in Pakistan through encouraging local people to engage in sustainable use of the forest that will ensure them long-term benefits, whilst permitting this unique area to survive along with its avifauna, of which the Western Tragopan is one spectacular example.

The Cheer was viewed with concern because it seemed to be widely scattered in tiny populations in habitats severely affected by man. Extensive surveys through much of the 1980's, carried out primarily by L. Young, R. Kaul, V. Sharma and S. Pandey, revealed that the species seems to thrive in early succession vegetation that is regularly grazed, cut for hay or burned. Indeed, the protection given to the Margalla Hills National Park near Islamabad in Pakistan led, over a decade or so, to the growth of scrub cover that is now too dense to be considered suitable habitat for the Cheer. The small size of the populations discovered around this time also seems to be natural and no great problem. Many sites were found where only a few pairs could be heard in chorus at dawn and dusk.

This species is also the only one in the family which has been the subject of a concerted reintroduction attempt, started

in the Margalla Hills, within sight of Islamabad. Birds were reared in Pakistan, from eggs laid by some of the large number of captive birds in Europe, and were subsequently released. Radio-tracking has shown that released birds can survive in the wild for as much as 18 months. However, despite about 15 years of effort, there is no evidence of a self-sustaining wild population being established and such a prospect seems so unlikely that the resources expended are being wound down; part of the problem may be the continually expanding city limits of Pakistan's capital. Later, when the first surveys of Cheer populations were conducted across the border in the Indian state of Himachal Pradesh, it was found that most Cheer Pheasants occurred at altitudes above the release site at Margalla. The lessons learned from this attempt are enormously valuable, though, and highlight the many difficulties of this course of action. The project has resulted in the formation of a conservation society in the Margalla Hills National Park,

Both races of the Crested Argus are considered to be threatened. The situation of the nominate, though, seems less worrying than was thought some time ago, as it has been found still to be locally common at several sites in Vietnam, and it occurs further south, and at higher altitudes than was previously thought. In addition, in 1994 it was found to be apparently common at a site in Laos where it was previously known only from some very old records.

[*Rheinardia ocellata ocellata*.
Photo: R. Seitre/Bios]

The Chinese Monal has traditionally been considered a threatened species, due to hunting pressure and habitat degradation caused by overgrazing in its rather restricted range. A recent study by Chinese ornithologists recorded the species at a minimum of 25 locations, seven of which are in protected areas, although the same study seems to confirm that the population is declining slightly. The species was practically unknown in captivity until the 1980's, but a captive breeding programme is now under way at Beijing Zoo, China, and San Diego Zoo, USA, and has borne its first successes. This species is easily distinguished from the other monals by the male's rich coppery mantle and the dark blue-green tail.

which will promote public awareness of the value of natural wildlife resources.

Reintroduction will, however, probably remain one of the last courses of action to be taken, because of the resources needed and the sort of detail on the species' ecological and behavioural requirements that are necessary to ensure that the reintroduction attempt stands any chance of success. Studies conducted on the Grey Partridge in southern England have shown that the behavioural development of birds raised in the absence of their mothers is quite seriously impaired and leaves them far more susceptible to predation.

In the years since then, WPA has broadened its horizons so that it now attempts to foster initiatives of any sort that will benefit Galliformes. The challenge is now defined for the Phasianidae and involves a number of urgent conservation issues. These include continued work towards identifying a suitable site for the long-term protection of the Sichuan Hill-partridge, and assessing its management needs in areas where commercial forestry is practised. Other applied questions that need addressing include the proposal of recommendations for managing Swamp Francolin habitat. At the other end of the scale are the Galliformes of Indonesia's protected areas. Current knowledge of their distribution, not to mention any aspect of ecology, is so poor that there is no clear idea of the extent to which existing protected areas will conserve large populations. Consequently, baseline surveys of the protected areas of Borneo and Sumatra are crucial first steps towards assessing the prospects of the species in question. Such measures are similarly required for most other birds on the two islands that are habitat specialists, suggesting that broad avifaunal surveys may be of greater value than searches for individual species or groups of species. In Africa, the dearth of information that exists on the forest Galliformes of southern Uganda should be remedied as soon as possible. Obviously, civil unrest in Angola and Djibouti rules out efforts in those two countries for the time being.

Other priorities for pheasants include further work on the Western Tragopan in the Palas Valley, which will benefit forest management there and elsewhere, and other management-related studies in China. Some of China's reserves which hold pheasants are quite small for these relatively large birds. Therefore, information is required to help guide the

management policies of these areas. China also holds some of the ornithologically least known areas in the world. Especially important is the area where Burma, China and India meet at the eastern end of the Himalayas. In addition to its several Endemic Bird Areas, this is one of the richest spots for Galliformes in the world, and also one of the least known. Surveys in eastern Tibet, south-western Sichuan and north-western Yunnan would help to produce a clearer picture of the current status of this region's birds, several of which are regional endemics.

There are many challenges ahead in the struggle to guarantee the survival of the world's pheasants, partridges, quails, francolins and snowcocks. However, the scale of the task has now been outlined, and a start has been made to address some of the major concerns.

PLATE 42

inches 8
cm 20

Subfamily PERDICINAE

Genus *LERWA* Hodgson, 1837

1. Snow Partridge

Lerwa lerwa

French: Lerva des neiges

German: Haldenhuhn

Spanish: Perdiz Lerwa

Taxonomy. *Perdix Lerwa* Hodgson, 1833, northern Nepal.

Eastern population has been separated in different subspecies, *major*, though doubtfully distinct. Monotypic.

Distribution. Himalayas from E Afghanistan through S & E Tibet to Assam and C China (S Gansu, NW Sichuan and N Yunnan).

Descriptive notes. 37-40 cm; 454-709 g. More barred dorsally than other Himalayan Galliformes; bright red bill and feet. Female almost identical, but slightly smaller than male; lacks spur and differs in intensity of bill colour, especially during breeding season. Immature less strikingly marked than adult, with broader barring on upperparts and head.

Habitat. Alpine meadows and open, rocky hillsides above tree-line with scattered rhododendron bushes and grasses, ferns and lichens, and also with snow patches. Usually between 3000 m and 5000 m, up to limit of permanent snow; rarely below 2500 m. In SW China found in all alpine habitats present: exposed rock with some lichens and sparse grass, and herb cover, including *Saussurea medusa*, *S. laniceps* and *Mecanopsis punica*; meadows, where flat terrain more densely covered by herbs and grasses, e.g. *Festuca ovina* and *Anaphalis longifolium*; and amongst shrubby grassland, where various *Salix* species and *Holcystrochiton tibeticum* can be found. Spring records evenly spread between these habitats.

Food and Feeding. Lichen, moss and other plant matter predominates. Seeds, flowers, leaves and shoots of 43 plant species recorded in SW China; grasses important, with most parts of several *Agrostis*, *Festuca* and *Polygonum* species taken, as well as herbs, e.g. gentians and *Potentilla*; also small amount of animal food. Forages in pairs or small groups.

Breeding. Lays from late May to mid-Jun in SW China. Monogamous and territorial. Nest is a hollow by cliffs or among alpine shrubs. Completed clutches of 2, 3 and 5 eggs recorded; incubation by female alone; in captivity, young reach adult weight at c. 100 days. Young birds stay with parents until following breeding season, and some still seen on territories as subadults; groups of up to 30 birds seen together later in year.

Movements. May descend in severe winters to 2100-2700 m from usual altitudes above 3000 m. In China remains above 3800 m; no altitudinal migration noted in Longmen Mts, SW China.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Was thought to be rare in China, but probably a consequence of its remote habitat being rarely visited and species remaining little known. Occupies sizeable range, with estimate of at least 100,000 km² of suitable habitat available; where present, generally considered to be common. This may suggest total population in order of hundreds of thousands; believed to be declining slightly. Threatened by habitat degradation and overexploitation; in Longmen Mts (SW China), human encroachment is considerable problem, with attendant poaching and herb collection disturbing nesting birds; species thought to have declined in W Himalayas, as palatability and tameness make it attractive target for hunters; in Pakistan now rare and local. Unlikely to be threatened in Bhutan. Whilst there is no need for immediate action, wildlife protection throughout species' range should be improved in order to halt decline in numbers. Known from three protected areas, Zayu Natural Reserve in Tibet, and Fengtongzai and Xiaozhaizigou Natural Reserves in Sichuan; probably occurs in others.

Bibliography. Ali (1962), Ali & Ripley (1980), Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Deng Wei-je (1990), Etchécopar & Hue (1978), Gaston *et al.* (1993), He Fen-qi & Cui Xie-zhen (1990), Inskipp & Inskipp (1985, 1986, 1993b), Li Xiang-tao & Lu Xiao-yi (1992), Ludlow & Kinnear (1944), Meinertzhagen (1927), Meyer de Schauensee (1984), Roberts (1991), Whitehead (1914).

Female similar to male but has outer webs of secondaries and secondary coverts mottled buff; lacks spurs.

Habitat. Upper coniferous forest, rhododendron scrub and alpine meadows between 3000 m and 4100 m; exposed rocky mountain slopes.

Food and Feeding. No information available.

Breeding. No reliable information available.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Lande: Insufficient information. Currently considered near-threatened. Legally protected species in China; was

thought uncommon, but probably a consequence of its remote habitat being rarely visited and the species remaining little known. Very little information available other than that species is now considered to be quite common although declining slightly. Habitat degradation is a threat and before other actions can be proposed, a baseline survey is needed to assess distribution and abundance.

Bibliography. Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Deng Wei-je (1990), Etchécopar & Hue (1978), He Fen-qi & Cui Xie-zhen (1990), Meise *et al.* (1938), Meyer de Schauensee (1984), Raethel (1988), Schönwetter (1967), Shi Dong-chou (1986).

3. Szechenyi's Monal-partridge

Tetraophasis szechenyii

French: Tétraphase de Szecheny

German: Rostkehl-Keilschwanzhuhn

Spanish: Perdiz-faisán Gorgiclara

Other common names: Buff-throated/Tibetan Monal-partridge/Partridge, Szechenyi's Pheasant-grouse/Pheasant-partridge/Partridge

Taxonomy. *Tetraophasis Szechenyii* Madarász, 1885, Sichuan or east Tibet.

Sometimes considered race of *T. obscurus*, with which forms superspecies. Monotypic

Distribution. E Himalayas, from extreme NE India and E Tibet to SC China (Sichuan and Yunnan).

Descriptive notes. c. 50 cm; two males 1020 g and 1500 g, one female 880 g. Present species and *T. obscurus* are amongst the most pheasant-like perdicines, with long tails that can be partially erected and spread when the birds are alarmed. Differs from *T. obscurus* by having chin, throat and foreneck pale fawn, rather than dark chestnut; has greyer rump and uppertail-coverts, and chestnut spots on underparts. Female similar to male, but slightly smaller and lacks spurs. Juvenile heavily barred black and brown on upperparts.

Habitat. Fir forest, rhododendron scrub and rocky gullies with cover in alpine zone; most-

ly in forest, but also occurs above tree-line in rocky alpine zone. Between 3300 m and 4600 m.

Food and Feeding. Small roots, small bulbs and green leaves.

Breeding. Only information available is that chicks were seen in Tibet from late May to Aug. and family groups of 6-12 noted.

Movements. No information on possible altitudinal migration. When flushed, flies downhill to cover.

Status and Conservation. Not globally threatened. Mace-Lande: Insufficient information. Currently considered near-threatened. Legally protected species in China was thought uncommon, but probably a consequence of its remote habitat being rarely visited and the species remaining little known. Apparently widely distributed in Qinghai, Xizang (Tibet), Sichuan and Yunnan, but distribution within known range may be very fragmented. Common in E Tibet; no information at all from NE India, which lies on edge of range. In past, assumed to be under some pressure from humans, such pressure might exist, but has not yet been identified. Baseline survey needed to assess distribution and propose future actions, if needed.

Bibliography. Ali & Ripley (1980), Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Etchécopar & Hue (1978), Harten (1912-1922), He Fen-qi *et al.* (1990), Ludlow & Kinnear (1944), Meyer de Schauensee (1984), Raethel (1988), Robson (1986), Schäfer (1934), Schönwetter (1967), Vaurie (1965d)

Genus *TETRAOPHASIS* Elliot, 1871

2. Verreaux's Monal-partridge

Tetraophasis obscurus

French: Tétraphase de Verreaux

Spanish: Perdiz-faisán Gorgioscura

German: Braunkehl-Keilschwanzhuhn

Other common names: Chestnut-throated Monal-partridge/Partridge, Verreaux's Pheasant-grouse/Pheasant-partridge/Partridge

Taxonomy. *Lophophorus obscurus* J. Verreaux, 1869, east Tibet = Mupin, Sichuan.

Sometimes considered conspecific with *T. szechenyii*, with which forms superspecies. Monotypic.

Distribution. W China, in NE Tibet, Qinghai, Gansu and Sichuan.

Descriptive notes. c. 47 cm; one male 938 g, two females 720 g and 840 g. Present species and *T. szechenyii* are amongst the most pheasant-like perdicines, with long tails that can be partially erected and spread when the birds are alarmed. Separated from *T. szechenyii* by having chin, throat and foreneck mainly dark chestnut, rather than pale fawn; has browner rump and uppertail-coverts.

Genus *TETRAOGALLUS* J. E. Gray, 1832

4. Caucasian Snowcock

Tetraogallus caucasicus

French: Tétragalle du Caucase

German: Kaukasuskönigshuhn

Spanish: Perdigallo Caucásiano

Taxonomy. *Tetrao caucasicus* Pallas, 1811, rocky heights of the Caucasus.

Has been included within a species group, the dark bellied snowcocks, with *T. caspius* and *T. himalayensis*. Monotypic.

Distribution. Caucasus, on main ridge and those to N.

Descriptive notes. c. 56 cm, male c. 1930 g, female c. 1730 g; wingspan 80-95 cm. Differs from other snowcocks in dark grey underparts with strong barring and scalloping on breast, nape rusty. Female duller than male, with more white in plumage, lacks spurs. Immature has plumage pattern less clearly marked.

Habitat. Mountain slopes adjacent to forest from 2500 m up to snow-line, in some areas from 1800 m, and mainly below 4000 m. Found on scree and rocky outcrops, but not in forest or scrub; avoids large tracts of snow cover.

Food and Feeding. Predominantly vegetarian, feeding on most plant parts (leaves, fruits, stems, tubers, etc.); nearly 40% of total weight in spring and summer made up by grasses such as *Poa* and *Festuca*; over 40% in remainder of year; 30-35% of species such as *Campanula*, *Alchemilla*, etc. Change in diet through year restricted to parts of plant eaten shoots and similar eaten when available; dry matter in autumn and winter. Young birds consume more legumes. When foraging, birds move up hillside; outwith breeding season usually in groups of 6-8 birds.

Breeding. Laying late Apr to Jul, including re-nests; nesting at upper altitudes up to 15 months later than at lowest altitudes; considerable variation between years in timing of commencement of courtship, but usually from early Apr. Believed to be monogamous. Nests in the open, or under a rock overhang. Lays 5-8 eggs, average 6.5; incubation c. 28 days, by female only; downy chicks are buff-coloured above, densely marked with sepia brown and black, pale cream below. Sexual maturity apparently reached at one year old.

Movements. Said to perform altitudinal migrations; in warm weather, after breeding, moves to higher altitudes, following line of perennial snows.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Included on USSR Red List in 1978. Despite small range, numbers now believed to be stable, in hundreds of thousands. In Azerbaijan is uncommon resident; total of 800-1000 birds (300-400 pairs) estimated in 1993; in 1990, 87 birds counted on Mt Babadag, and 115 in Zakataly Reserve. Only real threat is from habitat degradation caused by overgrazing by domestic stock. In Turkey, species occurs only in Arvin; hunting has been banned. Present in at least three protected areas, the Tebedzinski Reserve in Russia, the Zakataly Reserve in Azerbaijan and the Lagodechy Reserve in Georgia; occurs in Caucasus Endemic Bird Area.

Bibliography. Bannikov (1978), Baziev (1965, 1966, 1968, 1972, 1978), Bianki (1898), Cramp & Simmons (1980), Dementiev & Gladkov (1952), Fjeldså (1977), Flint *et al.* (1984), Hartert (1912-1922), Knystautas (1993), Kozlova (1952), Kuz'mina (1992), Patrikeev (1993), Potapov (1992b), Potapov & Flint (1989).

5. Caspian Snowcock

Tetraogallus caspius

French: Tétragaile de Perse German: Kaspikönigshuhn Spanish: Perdigallo del Caspio

Taxonomy. *Tetrao caspius* S. G. Gmelin, 1784, Astarabad, northern Iran.

Has been included within a species group, the dark-bellied snowcocks, with *T. caucasicus* and *T. himalayensis*. Population of Turkey and Armenia has been separated in different subspecies, *tauricus*, but doubtfully distinct. Two subspecies recognized.

Subspecies and Distribution.

T. c. caspius (S. G. Gmelin, 1784) - S & E Turkey through Armenia and NW Iran to S Transcaspiia. *T. c. semenowianschanskii* Zarudny, 1908 - Zagros Mts, Iran.

Descriptive notes. 55-61 cm; male 2500-2684 g, female 1800-2344 g; wingspan 95-105 cm. Similar to *T. caucasicus*, but appears greyer, and breast thinly spotted rather than barred. Female smaller and duller than male; lacks spurs. Immature has plumage pattern less clearly marked.

Habitat. Mountain slopes, mostly from 2400 m up to snow-line, but in some places down to 1800 m, and up to 4000 m. Found on scree and rocky outcrops, and occasionally down between tree-line and permanent snow areas, even descending among trees in late summer.

Typical habitat consists of steep slopes lacking snow cover, and gorges, crags and similar, with patches of snow and some herb and grass cover.

Food and Feeding. Believed to be vegetarian, with similar diet to *T. caucasicus*.

Breeding. Laying in late Apr and May; courtship usually begins in Apr. Believed to be monogamous. Nests in the open or under a rocky overhang. Normally 5-9 eggs laid; incubation 28-29 days, young hatching synchronously; chicks have cinnamon-pink and dark grey down above, whitish below; young raised by female alone; believed capable of precocial flight at 15-20 days. Sexual maturity apparently reached at one year old.

Movements. Mainly sedentary, but some altitudinal movement recorded in Turkey. In some areas does not descend at all, even in spells of heavy snow.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. CITES I. Included on USSR Red List in 1978. Seems to be poorly known. Based on extent of available habitat and abundance in some areas, total population estimated at 5000-15,000 birds. A more precise estimate of 8400-11,200 birds results from following figures: eleven populations were believed to hold fewer than 850 individuals in the Transcaucasus (Armenia and Azerbaijan) in 1978; 350 birds in Turkmenia in 1986; estimated 200-2000 individuals in Turkey, scattered in high mountains where status is uncertain, but species may be locally numerous; 7000-8000 birds in NW Iran. Pronounced decline in Armenia, Azerbaijan and Turkmenia at least; in Turkmenia, a dramatic population decrease occurred in Kopetdag Mts during late 1980's, attributed to poaching. Occurs in the Kafar and Dilijan Reserves in Armenia, Geygel Reserve in Azerbaijan and Kopetdag Reserve in Turkmenia. Threatened by overgrazing of its alpine habitat, which is easily reached by shepherds with guns, and with their sheep and dogs. In 1993 most of species' range in Azerbaijan was suffering with intensive military activity, and it was feared that poaching and spread of long range fire-arms could have drastic effects. Habitat protection is needed and an extensive survey should aim to locate healthy populations in Iran and Turkey. Species does not adapt well to captivity.

Bibliography. Bannikov (1978), Baziev (1972, 1978), Bianki (1898), Cramp & Simmons (1980), Dementiev & Gladkov (1952), Fjeldså (1977), Flint *et al.* (1984), Hue & Etchécopar (1970), Kiziroglu (1993), Knystautas (1993), Kozlova (1952), Kuz'mina (1992), Patrikeev (1993), Potapov (1992b), Potapov & Flint (1989), Schönwetter (1967), Vauce (1965d).

6. Himalayan Snowcock

Tetraogallus himalayensis

French: Tétragaile de l'Himalaya

German: Himalayakönigshuhn

Spanish: Perdigallo Himalayo

Taxonomy. *Tetraogallus himalayensis* G. R. Gray, 1843, Himalayas.

Has been included within a species group, the dark-bellied snowcocks, with *T. caspius* and *T. caucasicus*. Population of NW Afghanistan has been separated in race *bendi*, although usually included within *incognitus*. Five subspecies recognized.

Subspecies and Distribution.

T. h. sewerzowi Zarudny, 1910 - Tien Shan Mts N to Zaysan (E Kazakhstan) and E to Xinjiang (NW China).

T. h. incognitus Zarudny, 1911 - mountains of S Tajikistan and N Afghanistan.

T. h. himalayensis G. R. Gray, 1843 - E Afghanistan E to Ladakh (NW India) and Nepal.

T. h. grombchewskii Bianchi, 1898 - CW China, in W Kunlun Mts, N Tibet and S Xinjiang.

T. h. koslowi Bianchi, 1898 - WC China, in Nan Shan and Ching Hai Ku Mts of Qinghai and S Gansu.

Introduced successfully to North America (NE Nevada).

Descriptive notes. 54-72 cm; 2000-3629 g. Similar to *T. caspius* but breast paler and with more horizontal blackish streaking. Only member of genus with a thin brown collar at base of white throat. Female slightly smaller than male; lacks spurs; forehead buff, and area around eye is greyer. Immature paler, with less distinct markings, except for white supercilium. Races vary in general tone of plumage coloration, nominate darkest.

Habitat. Open mountain slopes from just below tree-line up to snow-line; steep alpine pastures and rocky ridges. In Pakistan, usually between 3900 m and 4570 m, but occasionally

below 3600 m; found in steep valleys and on mountain spurs at highest altitudes.

Food and Feeding. In Jul-Aug in Hunza, Pakistan, predominantly bulbous roots and tubers, *Ephedra* berries, grasses (*Poa*, *Alopecurus*), sedges, shoots and leaves. In winter takes variety of vegetable material from exposed slopes where snow does not persist, eating similar food to that consumed in summer; seeding grass heads form staple diet. Moves uphill during the day, foraging by raking the ground and digging with bill.

Breeding. Laying late Apr to mid-May; display in mid-Apr in Tien Shan Mts, W China. Monogamous and territorial. Nests amongst grass tufts near rock or boulder. Usually 8 eggs (5-10); incubation 30 days, by female alone; both parents raise young.

Movements. In general, reported to occur at 3600-5100 m in summer, moving down to 2100 m in winter. Where introduced in Nevada, USA, remains above 3000 m throughout winter; in winter, groups of 30-40 birds seen.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Overall status remains unclear. Very widespread with range possibly covering over 1,000,000 km². No detailed data available on numbers, but an informed estimate suggests total of more than 200,000 individuals, with population thought to be stable. Considered plentiful throughout large expanse of mountainous terrain in Pakistan, especially in Hunza, Gilgit and Baltistan; less common in Safed Koh range than some parts of Chitral, and sparse in Swat Kohistan. Scattered throughout ranges of C Afghanistan; rare in inner ranges of Nepal. In some places, overhunted for food. Occurs in the Issyk-Kul Reserve in Kirghizia. As much of distribution is in rugged and unpopulated regions, protected areas may not be essential to species' survival. Introduced population of North America estimated at 250-500 birds.

7. Tibetan Snowcock

Tetraogallus tibetanus

French: Tétragaile du Tibet

German: Tibetkönigshuhn

Spanish: Perdigallo Tibetano

Taxonomy. *Tetraogallus tibetanus* Gould, 1854, Tibet = Ladakh.

Has been included within a species group, the white-bellied snowcocks, with *T. altaicus*. Six races sometimes accepted, but *tshimenensis* included in nominate *tibetanus*, and *centralis* within *przewalskii*. Four subspecies currently recognized.

Subspecies and Distribution.

T. t. tibetanus Gould, 1854 - Pamirs and Tajikistan SE to W Tibet and Ladakh.

T. t. przewalskii Bianchi, 1907 - NE India to WC China (Qinghai, SW Gansu and NW Sichuan).

T. t. aquilonifer R. & A. Meinertzhagen, 1926 - W Nepal E to Bhutan.

T. t. henrici Oustalet, 1891 - E Tibet to NW Sichuan.

Descriptive notes. c. 50 cm; male 1500-1750 g, female 1170-1600 g. Separated from other snowcocks by extensive white underparts with heavy blackish streaks on flanks; head pattern also characteristic. Female smaller than male, with less well defined head and neck pattern; lacks spurs. Immature paler; plumage pattern less clearly marked, except for more conspicuous white supercilium. Races separated by colour of head, nape and back; *aquilonifer* darkest.

Habitat. Open slopes from 3700 m up to permanent snow-line. Up to c. 5800 m in W Himalayas in summer, where inhabits alpine pastures and stony ridges with sparse grass covering above tree-line.

Food and Feeding. Almost no specific information, but apparently similar to *T. himalayensis*; grasses and herbs taken include *Stellaria*, *Saxifraga*, *Oxytropis*, *Potentilla* and *Primula*.

Breeding. Season lasts from late May to early Jul (1 record of late Aug). Lays 4-5 eggs (4-7). Broods of 4-6 seen in mid-Jul. No further information available.

Movements. Up to 5800 m in summer months, moving down to 3000-4000 m in winter; apparently sometimes gathers in groups in autumn before descending.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. CITES I. Widely distributed, with range believed to be over 500,000 km²; detailed surveys in some areas indicate species may be fairly common, suggesting total population in hundreds of thousands; considered stable at present but irregular changes in number are reported. Possible threats, if any, have not yet been identified, so their significance for long-term survival of species necessarily remains unknown; no information on whether or not species occurs in any protected areas. Collection of baseline information on status is of prime importance.

Bibliography. Ali (1962), Ali & Ripley (1980), Baker (1930, 1935), Baziev (1978), Bianki (1898), Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Dementiev & Gladkov (1952), Deng Wei-jie (1990), Eichécopar & Hùe (1978), Flint *et al.* (1984), He Fen-qi & Cui Xie-zhen (1990), Inskipp & Inskipp (1985), King & Peng Ji-tai (1991), Knyshtaus (1993), Kozlova (1952), Kuz'mina (1992), Ludlow & Kinnear (1944), Mallon (1987), Marien (1961), Potapov (1966, 1992b), Potapov & Flint (1989), Robson (1986), Shen Xiao-zhou & Wang Jia-jun (1963), Yang Lan & Xu Yan-gong (1987), Zheng Sheng-wu & Pi Nan-lin (1979).

8. Altai Snowcock

Tetraoallus altaicus

French: Tétragalle de l'Altai **German:** Altaikönigshuhn **Spanish:** Perdigallo Altaico

Taxonomy. *Perdix altaica* Geblér, 1836, Argut River in Katun Mountains, Altai.

Has been included within a species group, the white-bellied snowcocks, with *T. tibetanus*. On occasion, two subspecies have been recognized, but *orientalis*, of NW Mongolia, probably not valid. Monotypic.

Distribution. S Siberia and Mongolia, in Sayan, Tuva and Altai Mts.

Descriptive notes. c. 57 cm; male c. 3000 g, female c. 2540 g. Similar to *T. tibetanus*, but white underparts are not streaked black, and breast spotted black, as opposed to blotched with white. Female smaller than male; lacks spurs. Immature similar to adult, but outer primaries pointed and worn.

Habitat. Steppes, alpine meadows and tundra in mountain ranges, from 400 m up to snow-line.

Food and Feeding. Tubers, bulbs, seeds, shoots (e.g. *Betula*), and berries, including *Berberis*; some insects also eaten.

Breeding. Lays c. mid-Mar, exact date depending upon weather, habitat and age of birds. Nest situated in gravel, and lined with feathers. Five clutches of 4, 6, 8, 8, 15 eggs; incubation 28 days, by female alone. Young breed in following season.

Movements. No altitudinal movement recorded, but on occasions of heavy winter snowfall birds will move horizontally to areas with less snow. Birds move about throughout the mountains.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Overall status remains unclear. Considered a rare and endangered species in USSR in 1978. Although range may amount to over 100,000 km², the naturally fragmented habitat probably covers a much smaller total area; occurs in a non-highlighted Endemic Bird Area. Total population estimated at 50,000-150,000 individuals, with numbers stable, increasing or decreasing, according to locality; apparently stable or declining overall. Main threats are overexploitation and a variety of pressures on habitat, e.g. degradation through overgrazing by domestic stock and conversion to agriculture, leading to increased fragmentation. Believed to be increasingly used in Tibetan medicine. Present in the Altai and Katun Protected Areas.

Bibliography. Bannikov (1978), Bianki (1898), Borodin *et al.* (1985), Dementiev & Gladkov (1952), Eichécopar & Hùe (1978), Flint *et al.* (1984), Fox (1990), Irisov (1991), Knyshtaus (1993), Kozlova (1952), Kuz'mina (1992), Lukianov (1992), Maleshin *et al.* (1981), Potapov (1992b), Potapov & Flint (1989), Rogacheva (1992), Shen Xiao-zhou & Wang Jia-jun (1963), Zong & Bold (1983).

Genus *ALECTORIS* Kaup, 1829

9. Arabian Partridge

Alectoris melanocephala

French: Perdrix à tête noire **German:** Schwarzkopf-Steinhuhn **Spanish:** Perdiz Árabe
Other common names: Arabian Red-legged Partridge

Taxonomy. *Perdix melanocephala* Rüppell, 1835, mountains near Jeddah, Saudi Arabia. Distinctive member of genus, sometimes separated in monotypic subgenus. Population from E Hadramut, Saudi Arabia, has been separated in different race, *quichardi*, but not widely accepted. Monotypic.

Distribution. S Arabia from Jeddah (W Saudi Arabia) S to Aden (Yemen) and E to Muscat (Oman). No acceptable record for Eritrea, where data may be based on released birds.

Descriptive notes. 40-43 cm; male c. 724 g, female c. 522 g. Differs from other *Alectoris* by larger size, grey tail feathers (visible in flight), and black crown. Female slightly smaller than male. First-winter bird similar to adult, but has short crest, blackish bill and possibly duller general appearance.

Habitat. Stony and somewhat better vegetated ground in hills, mountains and upland plains, from near sea-level to 3000 m, including montane juniper forest. In Oman, inhabits mountains, wadis and upland plains where there is vegetation; also visits cultivation.

Food and Feeding. Feeds on vegetable matter, seeds and invertebrates. Crops contained the grass *Schismus barbatus* and the herb *Gnaphalium pulvinatum*, as well as cereal seeds and insects; those from Aden with higher proportions of cultivated grain and about 15% insects. Forages and drinks in morning and evening.

Breeding. Lays late Mar in Arabia; formerly Jul-Aug in Eritrea, where now extinct, and in any case perhaps exotic. Nest usually sited over 600 m above sea-level, under cover. Usually 5-8 eggs (5-11).

Movements. No information available, but presumably sedentary. Escapes potential predators by running uphill.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Locally common in Saudi Arabia with highest densities in juniper forest; widespread but uncommon in Yemen; fairly common in Oman. Numbers assumed to be stable throughout range; recently reported from around Medina, thus extending range considerably. Occurs in Raydah Reserve within Asir National Park, Jebel Firqah Protected Area and several proposed protected areas. Whilst no threats are documented, species likely to be affected by pressures on its habitat, e.g. grazing by domestic stock and conversion to agricultural land, as well as periodical drought in places. Direct exploitation (hunting and collection of eggs) occurs, but not believed to have significant adverse effects at present. Juniper forest may be a key habitat, and areas should be set aside to protect this continually degraded habitat; any conservation initiatives should aim to assess the importance of juniper and propose management and protection measures.

Bibliography. Ash (1992), Gallagher & Woodcock (1980), Hollom *et al.* (1988), Mackworth-Praed & Grant (1957), Meinertzhagen (1949, 1954), Rahmani & Shobrak (1993), Randi, Alkon & Meriggi (1992), Randi, Meriggi *et al.* (1992), Rands *et al.* (1987), Watson, G.E. (1962a).

10. Przevalski's Partridge

Alectoris magna

French: Perdrix de Przevalski **German:** Przevalskisteinhuhn **Spanish:** Perdiz Magna
Other common names: Rusty-necklaced Partridge, Przevalski's Rock-partridge

Taxonomy. *Caccabis magna* Przevalski, 1876, Zaidam, Koko-nor (= Ching Hai Ku Mountains) and northern Tibet.

Formerly included in genus *Caccabis*; *C. hwanghoensis* is a synonym. Forms superspecies with *A. graeca*, *A. chukar* and *A. philbyi*. Has been considered a race of *A. graeca*. Monotypic.

Distribution. NC China (Qinghai and SE Gansu).

Descriptive notes. c. 38 cm; male 445-710 g, female 442-615 g. Pattern of collar unique among members of *Alectoris*: very narrow, mostly rusty brown with inner edge fuscous to black. Similar to *A. chukar* in dorsal colour, but closer to *A. graeca* in patterns of lores and flanks; differs from both in yellowish grey, rather than brown, eyes. Female only slightly smaller than male.

Habitat. Apparently occupies rocky hillsides and valleys covered with grass and small bushes from 1300 m to 4000 m.

Food and Feeding. Adults eat seeds, rhizomes, bulbs, seedlings and shoots; also some insects. Young birds consume mostly insects and green leaves.

Breeding. Lays from early May; pairing from late Mar to mid-Apr. Nests by cover in sunny locations on steep ground, or on cliffs of yellow soil ravines; nest is a simple hollow lined with grass, leaves, etc. Records of 7 clutches with 7-20 eggs, average 12.3; incubation 22-24 days under artificial conditions, by female alone. Both parents tend young, families staying together until next breeding season.

Movements. Altitudinal migration reported to occur in E Qinghai Plateau, but not in Yellow Soil Plateau.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Currently considered near-threatened. In NC China, densities vary from less than 4 birds/km² to over 14 birds/km², depending on habitat type, with yellow soil ravines around farmland and water the most favoured. Total population size likely to be in hundreds of thousands. Species has restricted range; occurs in Qinghai Mts Endemic Bird Area. Hunting is a major problem; species is persecuted throughout range and has been driven to extinction in some areas. A strategy for rational use should be devised to curtail this overexploitation before numbers drop excessively.

Bibliography. Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Elchécopar & Hue (1978), Liu Nai-fa (1984, 1992), Liu Nai-fa & Yang You-lao (1982), Meyer de Schauensee (1984), Raethel (1988), Randi, Alkon & Meriggi (1992), Watson, G.E. (1962a, 1962b).

11. Rock Partridge

Alectoris graeca

French: Perdrix bartavelle **German:** Steinhuhn **Spanish:** Perdiz Griega

Taxonomy. *Perdix graeca* Meisner, 1804, Greece.

Forms superspecies with *A. magna*, *A. chukar* and *A. philbyi*. Treatment of this species has varied considerably; has been considered to include *A. chukar* and *A. magna* in the past. Possibly hybridizes with *A. chukar* in some areas and with *A. rufa*, which is introduced in parts of France. Three subspecies recognized.

Subspecies and Distribution.

A. g. saxatilis (Bechstein, 1805) - Alps from France to Austria and W Yugoslavia; Apennines.

A. g. graeca (Meisner, 1804) - SE Yugoslavia to Greece and Bulgaria.

A. g. whitakeri Schiebel, 1934 - Sicily.

Indeterminate mixed populations of present species and *A. chukar* introduced into UK, Russia, USA, Canada, Mexico and New Zealand; Hawaiian birds known to derive from *A. chukar*.

Descriptive notes. 33-37 cm; male 550-850 g, female 410-650 g; wingspan 46-53 cm. Difficult to separate in field from *A. chukar*; slight differences in extent of black pattern on head, upper breast and flank feathers; upperparts generally more bluish grey, rather than brownish. Female slightly smaller than male, with duller head pattern and no tarsal knob. Immature smaller and much duller with less extensive patterning. Races separated mainly by tone of plumage coloration and flank pattern.

Habitat. Rocky hills and mountain slopes with calcareous rock, short grass, sparse shrub cover and some tree stands; from sea-level up

to 2400 m, exceptionally to 2700 m in Italy. In subalpine zone, usually above 900 m, commonly between 1200 m and 1500 m. Not normally in forest, but present in open woodlands of *Pinus*, *Larix* and *Juniperus* amongst others; prefers heathland, but also found widely in pastures, grassy areas and low scrub; occurs in rocky ground, e.g. scree slopes, escarpments and crags. Never very far from water.

Food and Feeding. Predominantly vegetarian, eating seeds, fruits and green material, but also some terrestrial invertebrates. Chicks, and females in spring, consume relatively high proportions of invertebrates, mainly adult and larval insects, e.g. Orthoptera (grasshoppers), Coleoptera (beetles), Diptera (flies), Lepidoptera (caterpillars) and Formicidae (ants). Contents of 11 stomachs in Yugoslavia included fruits and seeds of grapes, assorted plant matter and grasshoppers, ants and beetles; those from French Alps had leaves and shoots of 5 plant species, *Gentiana lutea* seeds, a grasshopper and a snail; contents of 19 stomachs in Albania contained insects (grasshoppers, ants, beetles, bugs), molluscs, a spider and an isopod.

Breeding. Lays from mid-May to June in Alps, late Apr to Jun in Greece; break up of winter flocks from Feb, with territories established in Mar-Apr. Normally monogamous with long-term pair-bonds; some instances of successive bigamy reported, and some exchange of partners. Nest-site believed to be chosen by male, scrape excavated by female; laying occurs only when territory established; dominant males hold largest territories. Normally 8-14 eggs; incubation 24-26 days by female alone; chicks have cream and dark brown down above, paler below; young fully grown at 90 days, adult weight at 120 days.

Movements. Altitudinal movements reported in mountain breeding areas, but birds may remain at breeding altitude of 1900-2700 m in winter, if snowfall not too heavy. Odd occurrences in Romania in past may be consequence of local movements.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Declining in most parts of its range; populations of c. 25% of localities in Italy lost since 1960's; thought to be stable at 7000-13,000 pairs in Greece; in Austria, where hunting was legal until 1968, still fairly common in W Carinthia, although bag records suggest numbers have declined in last 100 years; declining since about 1950 in France, where there are now 2000-3000 pairs in spring. Protected since 1990 in Turkey, as numbers have declined. In Austria, at least, species said to benefit from human presence in the hills (as do some of its predators), because it feeds close to settlements in winter; as humans have retreated from higher altitudes, so has present species. In the more typical Mediterranean part of its range, habitat loss and degradation are main pressures, mostly resulting from agricultural intensification and urbanization. Hunting, as well as direct effects, results in considerable pressure on habitat in some areas.

Bibliography. Bernard-Laurent (1986, 1988), Bernard-Laurent & Laurent (1984), Bernard-Laurent *et al.* (1992), Cramp & Simmons (1980), Dias (1992), Didillon (1988), Dragoev (1974), Fjeldså (1977), Glutz von Blotzheim *et al.* (1973), Gossow *et al.* (1992), Meinertzhagen (1954), Menzendorf (1976a, 1976b, 1976c, 1977, 1982), Niehammer (1942), Paganini & Meneguzzi (1992), Randi, Alkon & Meriggi (1992), Randi, Meriggi *et al.* (1992), Schonwetter (1967), Serez (1992), Simeonov *et al.* (1990), Spano (1978), Thomades *et al.* (1992), Watson, G.E. (1962a, 1962b).

12. Chukar

Alectoris chukar

French: Perdrix chukar **German:** Chukarhuhn **Spanish:** Perdiz Chukar
Other common names: Chukar/Chukor Partridge, Chukor

Taxonomy. *Perdix Chukar* J. E. Gray, 1830, India = Srinagar.

Previously placed in superspecies with *A. philbyi*, *A. barbara* and *A. rufa*, but now proposed to form superspecies with *A. magna*, *A. graeca* and *A. philbyi*. Has been included within *A. graeca*. *A. kakeik* is a synonym. Populations of Bulgaria and Crete have been separated in races *kleini* and *scotti* respectively, but usually included in *cypristes*; other proposed races are: *caucasica*, included in *kurdistanica*; *shestoperovi*, *laptevi* and *dementievi*, included in *koroviakovi*; and *obscureata*, included in *dzungarica*. Fourteen subspecies currently recognized.

Subspecies and Distribution.

A. c. cypristes Hartert, 1917 - SE Bulgaria E through Asia Minor to S Syria; S Aegean Is, Crete, Rhodes and Cyprus.

A. c. sinaica (Bonaparte, 1858) - N Syrian Desert S to Sinai Peninsula.

A. c. kurdistanica Meinertzhagen, 1923 - Caucasus S to Iran.

A. c. werae (Zarudny & Loudon, 1904) - E Iraq and SW Iran.

A. c. koroviakovi (Zarudny, 1914) - E Iran E to Pakistan.

A. c. subpallida (Zarudny, 1914) - Tajikistan.

A. c. falki Hartert, 1917 - Kazakhstan S to NC Afghanistan and E to NW China (W Xinjiang).

A. c. dzungarica Sushkin, 1927 - NW Mongolia, Altai Mts and E Tibet.

A. c. pallascens (Hume, 1873) - NE Afghanistan E through NW India to W Tibet.

A. c. pallida (Hume, 1873) - NW China (W & S Xinjiang).

A. c. fallax Sushkin, 1927 - NW China, in Tien Shan Mts of NW Xinjiang.

A. c. chukar (J. E. Gray, 1830) - E Afghanistan E to Nepal.

A. c. pubescens (Swinhoe, 1871) - China, from W Qinghai and W Sichuan NE through Inner Mongolia to Liaoning.

A. c. potanini Sushkin, 1927 - W Mongolia.

Indeterminate mixed populations of present species and *A. graeca* introduced to UK, Russia, USA, Canada, Mexico, and New Zealand; Hawaiian birds known to derive from present species.

Descriptive notes. 32-39 cm; male 510-800 g, female 450-680 g; wingspan 47-52 cm. Difficult to separate in field from *A. graeca*; slight differences in extent of black pattern on head, upper breast and flank feathers; upperparts generally browner, less bluish grey. Female slightly smaller than male, with duller head pattern and no tarsal knob. Juvenile even smaller than female, with head and flank patterns scarcely appreciable. Races mainly separated on coloration: those of more humid areas darker and more olive above, richer buff below; those of more arid areas paler and greyer above, paler yellow below.

Habitat. Bare stony slopes with short grass, sparsely covered with short shrubs. Usually semi-arid and arid areas, from low plains up to 3000 m, locally to 4500 m. From dry valleys and near cultivation to steepest slopes with scattered scrub and trees in Bulgaria; found in small patches of heavily grazed forest in Kashmir; in Pakistan found in great variety of habitats in arid, rocky and hilly land, often in degraded scrub in foothills with *Dodonea* and *Reptonia* bushes, and among *Juniperus* forest at 3300 m in Baltistan. Often near cultivation, e.g. on terraced valley sides.

Food and Feeding. Bulbous roots, grain and shoots of grass and cereals, and insects. During periods of high rainfall, grass seeds dominate diet, and during hard winters birds dig extensively for bulbs and rhizomes. In Bulgaria, nearly 400 adults from all seasons had eaten mainly grass seeds, especially *Agrostis minor* and *Setaria viridis*, also tobacco (*Nicotiana tabacum*) seeds and those of weeds in autumn; some ants and other insects in summer. In Kashmir, in October species takes grass seeds, primarily *Eragrostis* and *Brachiaria*, and small proportion of insects. Small chicks in Bulgaria eat mainly weed and grass seeds; 37% of items are insects, including weevils, bugs and caterpillars; insects, primarily ants, taken until Sept.

Breeding. Laying mid-Apr to May in Mediterranean, rarely late Mar. In S Asia, early Apr to mid-Jul according to altitude; season long in Pakistan, with dates depending on altitude and latitude, from late Mar in Salt Range, not until late Jun in Kaghan Valley, where downy chicks seen at 3300 m in early Jul; most nesting Apr to mid-May. Usually monogamous; bigamy occasionally reported in USA. Nest is scrape sometimes lined with grass, leaves, etc.; under shelter, such as bush or overhanging grass. Usually 7-12 eggs, but 6-9 quoted for drier areas in Pakistan, and 15-19 in Kashmir, where rainfall heavier; incubation 22-25 days; chicks have cream and brown down above, paler below. Failure of spring rains in Kashmir adversely affects breeding; in good rains, two clutches recorded.

Movements. Descends in winter from upper altitudes. In mornings birds work their way uphill foraging. Strong, fast flier, but only over short distances; if pressed will fly downhill. In California, USA, released birds moved up to c. 52 km over two years; movements of up to 3-5 km in search of water in a day reported.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Very widely distributed, both in native Palearctic range and also where introduced in USA. By 1980, populations considered locally reduced only in a few parts of its range, e.g. Greece (now believed stable at 11,000-16,000 pairs) and Lebanon; elsewhere mostly stable and locally increasing. In Azerbaijan, population reckoned to number 800,000 birds in 1955, but perhaps an overestimate; total estimated at 100,000-150,000 birds in 1993, apparently decreasing due to habitat loss, intensive hunting and poaching. In Pakistan much reduced in front ranges, some birds remaining in Kirthar Range in Sind, in parts of Salt Range, and in Margallas in Punjab; widespread in less accessible areas; population may fluctuate considerably. Total of c. 600,000 taken by hunters annually in USA, and 10,000 in Canada. Severe winters known to affect Turkish populations, and pesticides may now be a cause for concern; protected in Turkey since 1990. Suffering from habitat degradation in some areas.

Bibliography. Ali & Ripley (1980), Alkon (1979), Arnold & Ferguson (1962), Baker (1928), Bates & Lowther (1952), Bell & Summers (1982), Cheng Tso-hin (1987), Cramp & Simmons (1980), Dementiev & Gladkov (1952), Dias (1992), Eichécopar & Húe (1978), Flint *et al.* (1984), Gallagher & Woodcock (1980), Gaston *et al.* (1993), Glutz von Blotzheim *et al.* (1973), Goodman *et al.* (1989), Heinroth & Heinroth (1931-1933), Holmes (1986), Inskip & Inskip (1985), Kaul & Qadri (1989), Kuz'mina (1992), Lamba *et al.* (1987), Lever (1987), Liu Ming-yu *et al.* (1986), Mackie & Buechner (1951), Mallon (1987), Marchant & Higgins (1993), Meinertzhagen (1954), Menzendorf (1976a, 1976b, 1976c, 1977), Patrikeev (1993), Paz (1987), Pinshow *et al.* (1984), Portal (1924), Potapov & Flint (1989), Randi, Alkon & Meriggi (1992), Randi, Meriggi *et al.* (1992), Roberts (1991), Serez (1992), Simeonov *et al.* (1990), Stewart & Christensen (1971), Vaurie (1965J), de Vos & Karami (1977), Watson, G.E. 13. Philby's Partridge

Alectoris philbyi

French: Perdrix de Philby

German: Philbysteinhuhn

Spanish: Perdiz Gorginegra

Other common names: Philby's Rock-partridge

Taxonomy. *Alectoris philbyi* Lowe, 1934, Taif, Hejaz, SW Arabia.

Previously placed in superspecies with *A. chukar*, *A. barbara* and *A. rufa*, but now proposed to form superspecies with *A. magna*, *A. graeca* and *A. chukar*. Formerly included within *A. graeca*. Monotypic.

Distribution. SW Saudi Arabia and N Yemen.

Descriptive notes. 33-36 cm; one bird 441 g. Black chin, cheeks and throat differentiate present species from all other members of genus; otherwise very similar to *A. chukar*. Female slightly smaller than male, with duller head pattern and no tarsal knob.

Habitat. Arid rocky areas in montane regions; from 1400 m to 2950 m in Saudi Arabia and 2300 m to 3600 m in Yemen. Also occurs in highland cultivation. Similar habitat to *A. melanocephala*, but on slopes with more bush cover.

Food and Feeding. Believed to be similar to *A. melanocephala*.

Breeding. Season from late Mar. Clutch reported to be small; 5-8 eggs noted, but this observation is doubted.

Movements. No information available, but presumably sedentary.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Locally common in Saudi Arabia and scarce in Yemen. Restricted range; occurs in Arabian Mountains Endemic Bird Area. Population trend unknown, but probably stable. No real threats known, but habitat alteration may have an effect in some areas; hunting is not systematic, and therefore not considered deleterious. Remoteness of montane habitat is best safeguard of species at present.

Bibliography. Hollom *et al.* (1988), Meinertzhagen (1954), Raethel (1988), Rahmani & Shobrak (1993), Randi, Alkon & Meriggi (1992), Randi, Meriggi *et al.* (1992), Rands *et al.* (1987), Stagg (1985), Watson, G.E. (1962a).

14. Barbary Partridge

Alectoris barbara

French: Perdrix gabra

German: Felsenhuhn

Spanish: Perdiz Moruna

Taxonomy. *Perdix Barbara* Bonnatere, 1792, no locality = Morocco.

Previously placed in superspecies with *A. chukar*, *A. philbyi* and *A. rufa*; now considered to be more distant from the reconstituted superspecies of *A. magna*, *A. graeca*, *A. chukar* and *A. philbyi*. Proposed races *theresae* and *duprezi* included respectively in *barbara* and *spatzi*. Four subspecies recognized.

Subspecies and Distribution.

A. b. koenigi (Reichenow, 1899) - NW Morocco.

A. b. barbara (Bonnaterre, 1792) - N Morocco and N Algeria; Sardinia (possibly introduced).

A. b. spatzi (Reichenow, 1895) - S Morocco, C Algeria and S Tunisia.

A. b. barbata (Reichenow, 1896) - Libya and NW Egypt.

Successfully introduced (*koenigi*) to S Spain and Canary Is. Introductions in rest of Europe, USA and Australia either unsuccessful from outset or populations died out.

Descriptive notes. 34-38 cm; male c. 461 g, female c. 376 g; wingspan 46-49 cm. Differs from other *Alectoris* by chestnut brown crown and broad neck band. Female almost identical to male, and only slightly smaller. Juvenile more uniform and yellowish. Races differ mainly in flank pattern, and also in overall tone of plumage coloration.

Habitat. Rocky areas and arid hillsides, and shrubby and wooded habitats up to 3300 m in Atlas Mts, where inhabits xerophytic vegetation: in sandy dunes and shrubby stands along dry river beds; also citrus plantations, areas of cropland, palm, citrus and olive groves, ma-

quis and areas with *Eucalyptus*, *Euphorbia*, etc. In Morocco, numbers highest in mixture of woodland, clearings and crops. Occupies similar habitat to that of *A. rufa* and *A. graeca*, where these species are absent.

Food and Feeding. Diet varied, but primarily leaves, shoots, fruits and seeds of wide range of grasses and herbs; insects, especially ants, are important supplement. Leaves of *Salsola*, *Lycium* and *Asparagus*, as well as fruits of *Euphorbia*, comprise up to one third of stomach contents; succulent leaves provide moisture. Young commonly feed on ants.

Breeding. Lays late Feb to mid-Jun in Morocco; elsewhere dates believed similar, mostly Mar-May; breeding earlier in lowlands than in mountains; in very dry years, breeding may not occur at all in semi-arid areas. Monogamous; pair formation in spring, when male starts calling. Nest is a depression on ground, usually with lining and placed under cover. Lays 6-20 eggs (mean of 25 clutches, 11-3); incubation c. 25 days; downy chicks are brown and cream above, paler below, with well marked streak over eye.

Movements. Mainly sedentary, but descends from upper zones of Atlas Mts during heavy winter snows.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Has declined locally and is probably even extinct in some areas, e.g. coast of NW Egypt; elsewhere, in remote areas and where protected, common to abundant. Hunting pressure is main cause of local decreases in numbers throughout range, e.g. in Algeria, where occurs locally. The most important quarry species in N Africa; a rehabilitated area of 6500 ha near Rabat was restocked with some success during 1982-1991. Intensification of agricultural practices is also a major cause of declines in places.

Bibliography. Alaoui (1983, 1985, 1992), Bannerman (1963), Cramp & Simmons (1980), Eichécopar & Húe (1964), Fieldis (1977), Goodman *et al.* (1989), Hartert (1912-1922), Heim de Balsac & Mayaud (1962), Hollom *et al.* (1988), Lever (1987), Randi, Alkon & Meriggi (1992), Randi, Meriggi *et al.* (1992), Schönwetter (1967), Urban *et al.* (1986), Valverde (1957), Voous (1960), Wadsack (1992), Watson, G.E. (1962a, 1962b).

15. Red-legged Partridge

Alectoris rufa

French: Perdrix rouge

German: Rothuhn

Spanish: Perdiz Roja

Taxonomy. *Tetrao rufus* Linnaeus, 1758, southern Europe = north Italy.

Previously placed in superspecies with *A. chukar*, *A. philbyi* and *A. barbara*; now considered to be more distant from the reconstituted superspecies of *A. magna*, *A. graeca*, *A. chukar* and *A. philbyi*. Population of Corsica has been separated in race *corsa*, but usually included in *rufa*; race *australis* described from Gran Canaria (Canary Is), where species is introduced. Three subspecies recognized.

Subspecies and Distribution.

A. r. rufa (Linnaeus, 1758) - France, NW Italy, Elba and Corsica.
A. r. hispanica (Seoane, 1894) - N & W Iberian Peninsula.
A. r. intercedens (A. E. Brehm, 1857) - E & S Iberian Peninsula and Balearic Is.
Introduced in several parts of Europe (e.g. Britain), and several Atlantic islands (Madeira, Azores, Canary Is); unsuccessfully in USA and New Zealand.

Descriptive notes. 34-38 cm; male 480-547 g, female 391-514 g; wingspan 47-50 cm. Best distinguished from other *Alectoris* by black mottling on breast and sides of neck; white forehead also distinctive. Female slightly smaller than male, with duller head and throat and no tarsal spur. Immature smaller and much duller with less extensive patterning. Races very similar, differing mainly in tone of plumage colour.

Habitat. Apparently less specialized than other *Alectoris*, ranging from Mediterranean to humid temperate zones, but not in boreal, oceanic or arid zones; prefers lowland areas.

Avoids forest and wet areas if possible; uses habitats with a wide variety of soils and land uses, again more varied than congeners. Dry, hilly land with scattered small bushes up to about 1300 m in montane foothills, but apparently on rare occasions as high as 2000 m, especially in S; from inhospitable dry terrain on lower mountain slopes to marginal cultivation, cropland, orchards, woodland, etc.

Food and Feeding. Seeds, leaves and roots; grasses and legumes especially important in winter. In Spain, predominantly wild and cultivated grasses and forage legumes, mainly vetches, *Vicia*, and other seeds and fruits on occasion; also ants, grasshoppers and other insects. In Portugal, various seeds and roots, grass foliage (mainly *Poa*) and legumes; roots such as *Poa*, *Ranunculus* and *Leontodon* in Aug-Oct; from Oct, grass leaves and legumes enter diet and become main components during winter; insects 3% by volume on average, but 10% in summer.

Breeding. Lays late Apr to early May in Portugal; late Apr to May in England; May to mid-Jun in France. Monogamous, with long-term bonds; occasionally bigamous. Nest-site chosen by male; nest, constructed by male, is scrape in ground lined with fairly few pieces of vegetation. Average 11-12-12.7 eggs; male will incubate if female absent, but usually female alone incubates; some cases of double-brooding reported, with second clutch started shortly after first, and parents incubating one clutch each; incubation 23-24 days; chicks have rich brown and cream down above, paler below; young tended by both parents if only one clutch, each clutch by one parent if two; chicks brooded when small; precocial flight at c. 10 days; full adult size at 50-60 days; remain with parents through first winter. Sexual maturity in first year.

Movements. Mostly sedentary, but some descent to lower ground noted in winter months.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Believed to have declined considerably in its native range; following decline in Liguria, Piemonte and adjacent regions in NW Italy, now stable at c. 1000-2000 coveys. In Portugal, declining and now scarce towards coastal regions; 6,200,000-7,400,000 birds may be shot each year, amounting to over 60% of estimated potential population; habitat fragmentation due to urbanization and agricultural expansion is also a problem; illegal importations of *A. graeca* and *A. chukar* may also be causing problems through hybridization and competition. Most valuable gamebird in Spain, where widely distributed; fairly common to common in areas of suitable habitat where not overhunted; restocking with captive-bred birds frequent in hunting areas. Wild stocks in Britain, where introduced, may now number 750,000 birds.

Bibliography. Bannerman & Bannerman (1965, 1966), Bernard-Laurent (1988), Brun & Aubineau (1989), Bump (1958), Cramp & Simmons (1980), Dias (1992), Didillon (1988), Fjeldså (1977), Fontana (1992), von Frisch (1962), Glutz von Blotzheim *et al.* (1973), Goodwin (1953, 1954, 1958), Green, R.E. (1984), Jenkins (1957), Lever (1987), Lucio (1989, 1990, 1991), Lucio & Purroy (1985, 1987, 1992), Marchant *et al.* (1990), Menzendorf (1976a, 1976c), Pepin (1984), Potts (1989), Randi, Alkon & Meriggi (1992), Randi, Meriggi *et al.* (1992), Rands (1988), Ricci (1983), Schönwetter (1967), Simeonov *et al.* (1990), Spano *et al.* (1989), Vaurie (1965d), Voous (1960).

Habitat. Dry and stony foothills that are lightly vegetated or bare; occasionally on plateaux up to c. 2000 m; sand dunes in some areas. Found in warmer, lower areas than *Alectoris chukar* where they are sympatric. Usually below 100 m in fairly arid foothills of mountains, and in deserts; flatter terrain preferred, often close to water. Not in narrow ravines, around crags or amongst thick tree cover.

Food and Feeding. Predominantly shoots and leaves, seeds and berries; also some insects. The herb *Trigonella occulta*, and flies, ants and beetles also recorded. Seen foraging around horse and mule droppings.

Breeding. Laying mid-Apr to Jul in former USSR; Mar-Jul in Pakistan; pairs seen in early Apr in Turkmenistan, in Feb in Iraq. Apparently monogamous; male may remain with female and young, but up to 20 males seen in groups during breeding season. Nest sited on exposed ground, but sheltered by grass or rocks; occasionally in small hollow. Usually 6-9 eggs (5-14); sometimes two clutches; incubation at least 21 days, by female only; chicks have rather uniform pale buff down above, whitish below. Female alone, or both adults, raise young, broods occasionally merging.

Movements. Usually sedentary, not normally moving higher in summer; recorded descending to flat plains at base of Salt Range in Pakistan. Flies only when strongly pressed, as is very swift runner; if alarmed on hillside will fly downhill.

Status and Conservation. Not globally threatened. Mace-Lande: Insufficient information. No direct information available; occurs at low densities but is widespread, and parts of range are unlikely to be disturbed by humans. Some human activities may increase access to surface water which may benefit the species. Distribution in SE Turkey believed to have expanded from Iraq border country since 1950, for reasons unclear; hunting banned in Turkey.

Bibliography. Ali & Ripley (1980), Allouse (1953), Cramp & Simmons (1980), Dementiev & Gladkov (1952), Flint *et al.* (1984), Hollom *et al.* (1988), Hüe & Etchécopar (1970), Knystautas (1993), Kuz'mina (1992), Maron (1951), Meinertzhagen (1920), Roberts (1991), Vaurie (1965d), Williams & Williams (1929).

17. Sand Partridge

Ammoperdix heyi

French: Perdrix de Hey German: Arabisches Wüstenhuhn Spanish: Perdiz Desértica

Taxonomy. *Perdix Heyi* Temminck, 1825, Desert of Aqaba, Arabia.

Race *intermedia* sometimes included within nominate *heyi*. Four subspecies recognized.

Subspecies and Distribution.

A. h. heyi (Temminck, 1825) - Jordan Valley S to Sinai Peninsula and through W Saudi Arabia.

A. h. nicolli Hartert, 1919 - N Egypt, E of R Nile, S to C Egypt.

A. h. cholmleyi Ogilvie-Grant, 1897 - C Egypt, E of R Nile, S to N Sudan.

A. h. intermedia Hartert, 1917 - S Arabia, from Aden E to Muscat, Oman, and Musundam Peninsula (UAE).

Introduced unsuccessfully to Cyprus.

Descriptive notes. 22-25 cm; c. 181 g; wingspan 39-41 cm. Male differs from *A. griseogularis* by chestnut throat and lack of pale neck spots; white marks on face lack black edges. Female sandier and greyer than male, with fewer markings; similar to that of *A. griseogularis*, but has pinkish bars, rather than white spots, on side of neck. Juveniles of both sexes apparently resemble adult female. Races differ in strength of overall colouring, with S races darker, and in presence or absence, and size, of white marks on forehead and lores of males; *cholmleyi* and *nicolli* generally lack pale line on forehead and white loreal spot.

although some individuals of *nicolli* can have small loreal spot.

Habitat. Desert and semi-desert, usually on steep, rocky slopes with scattered vegetation; boulder strewn, sandy bottomed wadis near hills and in hills, up to ridges over 2000 m, and down to c. 400 m below sea-level in Dead Sea Depression. Most abundant in valleys with some vegetation; rarely in uninterrupted stretches of dry, flat, open or sandy desert.

Food and Feeding. Mixed diet of seeds, berries and insects; eats mostly seeds in summer; often takes berries of *Salvadora persica* and *Commiphora*, as well as seeds of *Acacia* and grasses. Also bulbs and green leaves.

Breeding. Lays in Apr in N Africa, and apparently in Apr in Arabian Peninsula. Probably monogamous. Nest is a shallow scrape under cover of bush or rock; 5-7 eggs; chicks have pale buff down above, whitish below.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Common in Oman, where population stable; widespread, common and probably stable throughout most of range in Saudi Arabia, UAE and Yemen; persecution probably very local. In NE Africa, status unclear in mid-1980's, but probably still at least frequent in most of range; no confirmed observations from Eritrea, despite some claims to the contrary. No specific threats known, partly because species inhabits areas considered inhospitable to humans; in Oman, drought, domestic stock grazing and urbanization all affect the species, but are not considered to pose threats.

Bibliography. Baker (1930), Benson (1970), Cramp & Simmons (1980), Etchécopar & Hüe (1964), Gallagher (1977), Gallagher & Woodcock (1980), Goodman *et al.* (1989), Hollom *et al.* (1988), Hüe & Etchécopar (1970), Jennings (1981), Kuz'mina (1992), Mackworth-Præd & Grant (1957), Meinertzhagen (1930, 1954), Par (1987), Pinshow *et al.* (1984), Richardson (1990), Schönwetter (1967), Urban *et al.* (1986).

Genus AMMOPERDIX Gould, 1851

16. See-see Partridge

Ammoperdix griseogularis

French: Perdrix si-si German: Persisches Wüstenhuhn Spanish: Perdiz Gorgigris

Taxonomy. *Perdix griseogularis* J. F. Brandt, 1843, Persia. Monotypic.

Distribution. SE Turkey and Iraq E to SE Uzbekistan, Tajikistan and Pakistan. Introduced unsuccessfully to USA.

Descriptive notes. 22-25 cm; 182-225 g; wingspan 40-42 cm. Male differs from that of *A. heyi* by having grey throat, pale neck spots and whitish eyestripe with black edges. Female similar to that of *A. heyi*, but white spots, rather than pinkish bars, on sides of neck. Juveniles of both sexes apparently resemble adult male, but with less clearly defined face pattern.

On following pages: 22. Swamp Francolin (*Francolinus gularis*); 23. Coqui Francolin (*Francolinus coqui*); 24. White-throated Francolin (*Francolinus albogularis*); 25. Schlegel's Francolin (*Francolinus schlegelii*); 26. Latham's Francolin (*Francolinus lathamii*).

Taxonomy. *Tetrao pondicerianus* Gmelin, 1789, Pondicherry, India.

Recently proposed reorganization of *Francolinus* retains only *F. francolinus*, present species. *F. gularis*, *F. pictus* and *F. pintadeanus* in *Francolinus*. Present species has been placed in monotypic genus *Ortygornis*. Population of Sri Lanka has been awarded separate race, *ceylonensis*, but usually included within nominate. Three subspecies recognized.

Subspecies and Distribution.

F. p. mecranensis Zarudny & Härms, 1913 - SE Iran, Oman and S Pakistan.

F. p. interpositus Hartert, 1917 - S Pakistan (E Sind) through Nepal to NE India (Bihar and W Bengal). *F. p. pondicerianus* (Gmelin, 1789) - S India and NW coast of Sri Lanka.

Introduced into Amirante Is, Mauritius, Reunion, Seychelles, Rodrigues and Hawaiian Is; introduced populations of Andaman Is and Diego Garcia I now extinct.

Descriptive notes. 33-35 cm; male c. 274 g, female c. 228 g. Most uniformly and finely patterned Asian francolin; throat pattern, buffy throat fringed with black characteristic; chestnut outer rectrices are conspicuous in flight. Female similar to male, but lacks spurs. Immature similar to adult, but less clearly marked on head and throat. Races separated on pale to dark body coloration; *mecranensis* palest.

Habitat. Grassland and semi-thorny scrub; dry rolling plains and plateaus, especially in areas near village crops. Dryland conditions and degraded country with thorn scrub, often near scattered jowar, bajra and lentils, among other dry season crops. Can survive far from nearest water.

Food and Feeding. Seeds of weeds and cereals, grass and crop shoots, berries and drupes (*Zizyphus jujuba*, *Z. oenopia*, *Lantana*, *Capparis aphylla*); also takes insects, including grasshoppers, termites and maggots. Digs up small lizards (*Hemidactylus*, *Lacerta*) and succulent rhizomes of grasses.

Breeding. Eggs reported in every month in S Asia, but mostly Mar-Apr in Pakistan; nesting from Jan in Oman. Monogamous. Nest is a scrape, lined with grass and leaves; usually placed under cover, but sometimes exposed, in fields, shrubby gullies, hedges and amongst cacti; in Pakistan nest placed in grass clump within thorn bush. Lay 6-9 eggs; incubation 18-19 days, by female only. Both parents believed to raise young, with families staying together until autumn.

Movements. Sedentary. Flies only when very hard pressed, preferring to escape by running from bush to bush; when on the wing, alternates quick, strong flaps with glides of 50-100 m.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Very widely distributed, occurring in suitable habitat in an area over 1,000,000 km² in size. Common in Oman, where probably increasing its range by spreading into desert cultivation. Common in Pakistan, where large numbers taken for cage bird trade: widespread throughout Indus plains. Status in Nepal lowlands uncertain; common at Kohalpur in SW, and reported from several other sites. Major part of range is in India, where species is common and widespread throughout W & C India. Most frequent gamebird in most of its range, partly due to ability to inhabit a wide variety of arid vegetation types, and also to its tolerance of human activities. Pressures are mainly those affecting habitat, notably in form of degradation; pesticides connected with intensification of agriculture may be a problem in some areas.

Bibliography. Ali & Ripley (1980), Baker (1930, 1935) Bump & Bump (1964), Crowe & Crowe (1985), Crowe *et al.* (1992), Faruqi *et al.* (1960), Gallagher & Woodcock (1980), Hall (1963), Henry (1971), Hollom *et al.* (1988), Hue & Eichécor (1970), Inskipp & Inskipp (1985), Kaul & Howman (1991), Lever (1987), Meinertzhagen (1954), Phillips (1978), Richardson (1990), Roberts (1991), Sankar *et al.* (1993), Zacharias & Gaston (1993).

22. Swamp Francolin

Francolinus gularis

French: Francolin multiréa **German:** Sumpffrankolin **Spanish:** Francolín Palustre
Other common names: Swamp Partridge

Taxonomy. *Perdix gularis* Temminck, 1815, vicinity of Calcutta.

Recently proposed reorganization of *Francolinus* retains only *F. francolinus*, *F. pondicerianus*, present species, *F. pictus* and *F. pintadeanus* in *Francolinus*. Monotypic.

Distribution. NC India (Uttar Pradesh) and Nepal E to NE India (Assam) and Bangladesh.

Descriptive notes. c. 37 cm; male c. 510 g. Differs from other Asian *Francolinus* in strongly contrasting white stripes on underparts and rusty throat and foreneck. Chestnut outer tail feathers conspicuous in flight. Female similar to male, but lacks spur and has duller tarsus.

Habitat. Wet grasslands in low-lying land of terai and belt of alluvial plains; land prone to flooding in areas adjacent to Ganges and Brahmaputra river systems. In tall, dense grassland near marshy and swampy areas; also in sugar cane plantations around standing water in some areas, and in paddyfields.

Food and Feeding. Seeds of weeds and cereals, mustard, rice and other crop shoots; also insects. Emerges from tall grassland and cultivation, especially sugar cane, to forage on tracks with very short grass and around marshes in early morning and late afternoon.

Breeding. Lays from late Feb or Mar to May, mainly late Mar to Apr. Apparently monogamous. Nest is apparently often placed amongst reeds standing in water, in which case constructed from reeds, etc; alternatively at marsh edge, where nest is a more rudimentary structure. Normally 3-4 eggs (3-6); incubation by female only.

Movements. Sedentary, but will move to dry ground when low-lying areas around marshes are flooded. Flies out to feed on spring mornings, calling whilst in flight. Prefers to escape by running.

Status and Conservation. VULNERABLE. Mace-Lande: Vulnerable. Occurs in highly fragmented *terai* grassland. Locally common, but possibly as few as 1000-10,000 individuals remain, according to figures based on anecdotal information and some surveys. Recently reported from 12 protected areas (wildlife reserves, reserve forests, and national parks) in N India, ranging in size from 11 km² to 614 km², although extent of suitable habitat within each is unknown and probably very much smaller; suspected to occur at other localities. In Nepal, little suitable habitat now remains; recently recorded at Royal Sukla Phanta and Kosi Tappu Wildlife Reserves, and Royal Bardia National Park. Definitely declining outside protected areas due to habitat destruction, and appears for sale in markets in Lucknow from time to time, as is a popular pet in some parts of India. No recent records from Bangladesh, but could still occur in small numbers. May be dependent

upon protected areas for survival in long term, because of drainage of marshy areas for agricultural and other uses elsewhere; current protected area management is designed to benefit ungulates and may not be appropriate for present species. Likely to be affected by pesticides in run-off, where agriculture becomes intensive. Currently the subject of a detailed study designed to assess its distribution within and outwith protected areas, to investigate its use of sugar cane plantations, and to propose appropriate management techniques in protected areas.

Bibliography. Ali & Ripley (1980), Baker (1930, 1935), Collar & Andrew (1988), Crowe (1993), Crowe & Crowe (1985), Crowe *et al.* (1992), Hall (1963), Harvey (1990), Inskipp (1989), Inskipp & Inskipp (1986, 1985), Javed & Rahmani (1991), Kaul & Kalsi (1990), Rahmani & Qamar (1993), Sarker (1986), Shrestha (1992).

23. Coqui Francolin

Francolinus coqui

French: Francolin coqui **German:** Coquifrankolin **Spanish:** Francolín Coqui

Taxonomy. *Perdix Coqui* A. Smith, 1836, near Kurrichane, Transvaal.

Forms superspecies with *F. albogularis* and *F. schlegelii*; latter has been considered a race of present species. Recently proposed reorganization of *Francolinus* places present species in genus *Peliperdix* with *F. albogularis*, *F. schlegelii*, *F. lahami* and *F. sephaena*. Many other races have been described, but are currently considered doubtfully valid: *buckleyi* included in *spinetorum*; *thikae* in *maharao*; and *campbelli*, *vernayi*, *hoeschianus*, *angolensis*, *kasaicus* and *ruandae* in nominate *coqui*. Four subspecies recognized.

Subspecies and Distribution.

F. c. spinetorum Bates, 1928 - W Africa.

F. c. maharao W. L. Sclater, 1927 - Ethiopia, Kenya and N Tanzania.

F. c. hubbardi Ogilvie-Grant, 1895 - W & S Kenya S to Mwanza Province, Tanzania, and E to Kitui.

F. c. coqui (A. Smith, 1836) - NW Uganda S through Zaire and C Tanzania to C South Africa.

Descriptive notes. 20-25 cm; male 227-284 g, female 218-259 g. Male's uniformly ochre-coloured head contrasts sharply with barred breast; differs from *F. schlegelii* by lack of rufous on upperparts, which instead show dense barring, reminiscent of that found in *Coturnix*. Female has characteristic black and white face pattern. Immature similar to adult female, but paler, with more mottled rather than streaked upperparts; underparts more faintly barred. Races separated mainly by colour and pattern of underparts.

Habitat. Wide variety of grassy habitats, including savanna and wooded grassland, especially miombo woodland, up to 2200 m. Also found in sandy areas with bushes in drier country; frequents agricultural areas, but not considered a pest. Avoids hilly and stony land.

Food and Feeding. Seeds, including those of grass and grain, and leaves; also takes a variety of insects, including ants, beetles and larvae of other insects.

Breeding. Lays Jul in Nigeria; late Aug to Mar in Zaire; Oct-Apr (peak Nov-Feb) in South Africa; and possibly May-Jun in Ethiopia. Monogamous, and believed to be territorial. Nest is a slight hollow lined with grass, leaves and the like, at base of cover. Usually 4-5 eggs (2-8); chicks have buff and brown down above, buffy white below. Young stay with adults for several months; high predation rate.

Movements. Sedentary. Flies only when strongly pressed, preferring to escape by running.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. One of Africa's most widespread *Francolinus*, occurring in suitable habitat throughout an area of nearly 4,500,000 km². The only quantitative information available on abundance is that the mean density of five sites within Lake Mburo National Park, Uganda, was 3 birds/km² in 1980's. Abundance varies throughout range; uncommon and locally distributed in some parts of range, and common elsewhere. Specifically noted as rare in Mali, and uncommon to common in Ethiopia. Uncommon in Kruger National Park, South Africa. In Zimbabwe, hunting season should be limited to Jul-Sept. May be affected by disease, such as fowl pox, in some areas; known to be sensitive to state of grass cover, and disappears when areas are burnt or overgrazed.

Bibliography. Ash (1992), Bannerman (1953), Benson (1963), Benson & Benson (1975), Britton (1980), Clancey (1967, 1971), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Ginn *et al.* (1989), Hall (1963), Hartley & Mundy (1992), Jackson & Sclater (1938), Komen (1991b), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957-1973), Maclean (1993), Meyer (1971b), Pinto (1983), Pomeroy & Abe (1992), van Someren (1925-1935), Tait (1989), Urban *et al.* (1986), Vincent (1934), Woosnam (1912).

24. White-throated Francolin

Francolinus albogularis

French: Francolin à gorge blanche **German:** Weikehlfrankolin **Spanish:** Francolín Gorgiblanco

Taxonomy. *Francolinus albogularis* Hartlaub, 1854, Gambia.

Forms superspecies with *F. coqui* and *F. schlegelii*. Recently proposed reorganization of *Francolinus* places present species in genus *Peliperdix* with *F. coqui*, *F. schlegelii*, *F. lahami* and *F. sephaena*. Doubtfully valid races *meinerthageni* and *gambagae* included respectively in *dewittei* and *buckleyi*. Three subspecies recognized.

Subspecies and Distribution.

F. a. albogularis Hartlaub, 1854 - Senegambia to Ivory Coast.

F. a. buckleyi Ogilvie-Grant, 1892 - E Ivory Coast E to Cameroon.

F. a. dewittei Chapin, 1937 - SE Zaire, NW Zambia and E Angola.

Descriptive notes. c. 23 cm; 263-284 g. Distinguished from other members of the red-tailed group by unbarred chestnut and buff underparts. Female has narrower creamy streaking on back and fine barring on breast and flanks. Immature similar to adult female, but usually with more barred underparts. Races separated mainly on pattern and colour of underparts and supercilium.

Habitat. Open, rolling savanna, especially disturbed areas, such as recently burned land, and along trails and in scrub on abandoned cultivation. In W Africa, apparently is not usually found far from cover, even when in cultivation.

Food and Feeding. A variety of insects, including grasshoppers and termites, and plant material, including grass seeds.

Breeding. Lays in Jun in Nigeria, Sept-Oct in Senegal and Gambia, and Oct-Dec in S Zaire. Probably monogamous. Nest is a slight hollow, lined with grass, leaves, etc. Usually 6 eggs (4-7); chicks have buff and brown down above, paler below.

Movements. Sedentary. Flies only when very pressed, preferring to escape by creeping through vegetation.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Widespread, occurring in suitable habitat throughout an area of over 1,000,000 km²; considered safe by virtue of large range and tolerance of disturbed habitats. Locally distributed and considered uncommon to rare throughout most of range; locally not uncommon in Ghana; only one recent record from Gambia. No further information available.

Bibliography. Bannerman (1953), Benson (1963), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Elgood (1982), Gore (1990), Grimes (1987), Hall (1963), Jensen & Kirkeby (1980), Komen (1991b), Lippens & Wille (1976), Mackworth-Præd & Grant (1962, 1970), Morel & Morel (1990), Pinto (1983), Urban *et al.* (1986).

25. Schlegel's Francolin

Francolinus schlegelii

French: Francolin de Schlegel **German:** Schlegelfrankolin **Spanish:** Francolín de Schlegel

Taxonomy. *Francolinus Schlegelii* Heuglin, 1863, Bongo River (= Bussere River), Bahr-el-Ghazal, Sudan.

Previously considered a race of *F. coqui*. Forms superspecies with *F. coqui* and *F. albogularis*. Recently proposed reorganization of *Francolinus* places present species in genus *Peliperdix* with *F. coqui*, *F. albogularis*, *F. lathamii* and *F. sephaena*. Monotypic.

Distribution. WC Cameroon E through N Central African Republic and S Chad to SW Sudan.

Descriptive notes. 21-24 cm; male c. 251 g, female c. 223 g. Usually more rufous than *F. coqui* and lacks white throat of *F. albogularis*. Female has browner back with narrower creamy streaking; also irregular belly markings. Immature similar to adult female, with barred scapulars and mantle.

Habitat. Savanna woodland, especially where tree *Isoberrinia doka* is numerous and grass cover plentiful. Not found near human settlements.

Food and Feeding. Takes leaves of *Isoberrinia doka*, and seeds of grass and grain; also feeds on caterpillars.

Breeding. In Sudan lays in Sept-Nov. Probably monogamous. Nest is a slight hollow lined with grass, leaves, etc. Usually 2-5 eggs; one record of 10 eggs is probably erroneous. No further information available.

Movements. Sedentary. Flies only short distances, remaining silent in process.

Status and Conservation. Not globally threatened. Mace-Lande: Insufficient information. Considered a candidate for inclusion in Red Data Book in 1985. A very poorly known species, that appears usually to stay far from human settlements. No surveys have been conducted and there is little recent information, but species is generally regarded as uncommon to rare and local. Possible threats are not documented. Extensive surveys required throughout range. It may prove necessary to manage the savanna habitat in some areas.

Bibliography. Bannerman (1953, 1957), Cave (1949), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1963), Komen (1991b), Louette (1981), Mackworth-Præd & Grant (1957, 1970), Nikolaus (1987), Traylor (1960), Urban *et al.* (1986).

26. Latham's Francolin

Francolinus lathamii

French: Francolin de Latham **German:** Lathamfrankolin **Spanish:** Francolín Cariblanco
Other common names: (Latham's) Forest Francolin

Taxonomy. *Francolinus Lathamii* Hartlaub, 1854, Sierra Leone.

Recently proposed reorganization of *Francolinus* places present species in genus *Peliperdix* with *F. coqui*, *F. albogularis*, *F. schlegelii* and *F. sephaena*. Two subspecies recognized.

Subspecies and Distribution.

F. l. lathamii Hartlaub, 1854 - Sierra Leone E to W Zaire and S to Cabinda, Angola.

F. l. schubotzi Reichenow, 1912 - W Zaire E to extreme SW Sudan, W Uganda and extreme NW Tanzania.

Descriptive notes. c. 23 cm; one male 254 g, one female 284 g. Male very dark; black throat contrasts conspicuously with white spotting below, a combination unique in *Francolinus*; recalls *F. nahani*, but lacks red facial skin, white throat and red legs. Female much browner. Immature similar to adult female, but more rufous above and whiter below. Male *schubotzi* has greyer face patch than nominate *lathamii*; that of female is more rufous.

Habitat. Equatorial lowland forest belt; primary forest, up to 1400 m in Uganda; occasionally also in secondary forest, sometimes far from primary forest, e.g. in Sierra Leone; uses gallery forest in Sudan, and coastal thicket in Ghana.

Food and Feeding. Termites (*Basidentitermes*), ants (*Psalidomyrmex*) and other arthropods, snails, beetles and similar comprise 90% of diet; 10% fruits, seeds and green leaves.

Breeding. Lays in Feb and Dec in W Cameroon; Dec (dry season) in S Cameroon; Dec-Apr in Zaire; Aug in Uganda; eggs recorded in Jan-Feb in Sierra Leone, in Feb in Ghana. Probably monogamous. Eggs laid on dry leaves between buttress roots of forest tree. Usually 2 eggs (2-3); chicks have chestnut brown down above, dark buff below. 80% hatching success in one study.

Movements. Sedentary. Flies only when very pressed, preferring to escape by running. Typical flight is short and fast.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Widespread, occurring in suitable habitat throughout an area of over 2,000,000 km². Only information on abundance is that species is generally uncommon, but locally common; not uncommon in Sierra Leone and Ghana; not often recorded in Uganda. Threatened by forest loss and easily caught by termite-baited snares, and shot at grain-baited sites. Known from at least six protected areas, Bugoma, Budango, Kalinzu, Kibale, Semliki and Mabira Forest Reserves, ranging in size from 137 km² to 793 km²; these areas are generally effective in conserving the species. Whilst there appears to be no immediate cause for concern, there is an obvious need to establish status of species in more detail, and to monitor extent of threats.

Bibliography. Bannerman (1930, 1953, 1957), Britton (1980), Brosset (1974), Chapin (1932), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Grimes (1987), Hall (1963), Komen (1991b), Lippens & Wille (1976), Mackworth-Præd & Grant (1957, 1970), Pinto (1983), Rodewald *et al.* (1994), Serle (1981), Thiollay (1971, 1973a, 1973b), Urban *et al.* (1986).

27. Crested Francolin

Francolinus sephaena

French: Francolin huppé German: Schopffrankolin Spanish: Francolin Capirotado

Taxonomy. *Perdix Sephaena* A. Smith, 1836, Marico River and Limpopo River, western Transvaal. Recently proposed reorganization of *Francolinus* places present species in genus *Perdix* with *F. coqui*, *F. albogularis*, *F. schlegelii* and *F. lathami*. Has been included with *F. streptophorus* in genus *Dendroperdix*. Race *rovuma* has been considered separate species, but hybridizes extensively with *spilogaster* in Kenya; this tendency has been attributed to destruction of habitat by humans. Five subspecies recognized.

Subspecies and Distribution.

F. s. spilogaster Salvadori, 1888 - E Ethiopia, Somalia and NE Kenya.
F. s. grantii Hartlaub, 1866 - S Sudan and W Ethiopia S to NC Tanzania.
F. s. rovuma G. R. Gray, 1867 - Kenyan coast S to N Mozambique.
F. s. zambezie Mackworth-Praed, 1920 - WC Mozambique W to NW Namibia and S Angola.
F. s. sephaena (A. Smith, 1836) - SE Botswana, SE Zimbabwe, S Mozambique and NE South Africa.

Descriptive notes. 30-35 cm; male 308-417 g, female 225-353 g. Chestnut blotching on neck and breast, black bill, red legs, white supercilium and dark brown crown distinctive; running bird often cocks tail and raises crown feathers. Female slightly smaller, with upperparts more densely barred. Immature similar to female but paler. Considerable variation, both individually and geographically, mostly in size and underpart coloration; race *rovuma* has blotching extended over most of underparts.

Habitat. Variety of brushland habitats with sparse ground cover including dense bushes

along rivers. *Acacia/Commiphora* woodland, forest edge and overgrown cultivation. In some areas can be found far from water, although often considered predictor of nearby water source; recorded up to 2200 m in Somalia.

Food and Feeding. Termites, other insects and their larvae, sedge bulbs and grasses, and a variety of other plant material; probably berries, molluscs and other food, as available. Seen foraging on elephant droppings.

Breeding. Lays Oct-Mar in South Africa; Jun-Jul in Mozambique; Mar-May in Ethiopia, and mainly May-Jun in Somalia. Probably monogamous. Nest is a hollow lined with grass and leaves at base of cover, well hidden. Usually 6 eggs (4-9); incubation c. 19 days; downy chicks are rufous brown, black and buff above, buffy white below.

Movements. Sedentary. Escapes by running in areas with little vegetation, but will flee mammalian predator by flying up into bush or tree; flight very fast, but not usually far.

Status and Conservation. Not globally threatened. Mace-Land: Safe. One of Africa's most widespread *Francolinus*, occurring in suitable habitat throughout an area of nearly 4,500,000 km². Locally common to abundant and probably stable throughout range; probably most widespread and plentiful gamebird in Kenya; uncommon in Kruger National Park, South Africa. No further information available on abundance. Not considered threatened anywhere, but habitat degradation and possibly conversion of savanna to agricultural land may affect the species; was considered to have declined in heavily populated Kisumu and in the coastal strip in Kenya in 1930's, as a result of habitat changes and shooting. Hunted in Zimbabwe, where shooting should be restricted to period Jul-Sept.

Bibliography. Archer & Godman (1937), Ash (1992), Ash & Miskell (1983), Benson (1963), Britton (1980), Clancy (1967), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Ginn *et al.* (1989), Haagner (1913b), Hall (1963), Hartley & Mundy (1992), Jackson & Selaier (1938), Komen (1991b), Lack (1985), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1957-1973), Maclean (1993), Pinto (1983), Pomeroy & Abe (1992), Snow (1978), Swank (1977), Urban *et al.* (1986), Vincent (1934).

28. Ring-necked Francolin

Francolinus streptophorus

French: Francolin à collier German: Kragenfrankolin Spanish: Francolin Acolarado

Taxonomy. *Francolinus streptophorus* Ogilvie-Grant, 1891, Mangiki, Mount Elgon, Kenya. Forms superspecies with *F. africanus*, *F. levaillantii* and *F. finschi*. Recently proposed reorganization of *Francolinus* places present species in genus *Sclerophila* with *F. finschi*, *F. levaillantii*, *F. africanus*, *F. psilolaemus*, *F. shelleyi* and *F. levaillantoides*. Has been included with *F. sephaena* in genus *Dendroperdix*. Monotypic.

Distribution. Disjunct distribution, with four separate populations: in Uganda, from Kidepo National Park W to R Nile and S Katonga Valley and at base of Mt Moroto; in Kenya, from S slopes of Mt Elgon to Samia Hills and Nyando Valley; in NW Tanzania, in Kibondo and Kasulu districts; and an isolated population in highlands of Cameroon.

Descriptive notes. c. 33 cm; two males 364 g and 406 g. Distinctive black and white barring on upper breast extends round onto hind-neck. Female has dark brown crown and barred upperparts.

Habitat. Sparsely vegetated hillsides from 600 m to 1800 m, with thin covering of grass amongst rocks; occurs at 1050-1200 m in Cameroon; also affects wooded grassland and cultivation.

Food and Feeding. Known to eat insects and seeds and may visit cultivated areas, presumably to feed on weeds, crops and insects.

Breeding. Lays during early rains in Apr in Uganda; in dry season, Dec-Mar, in Kenya. Probably monogamous. Nest is a slight hollow with a sparse lining, often situated at the base of a rock. Usually 4-5 eggs.

Movements. Sedentary. Flies very fast, but usually runs into cover when alarmed.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Occurs in suitable habitat throughout an area of c. 150,000 km². Was considered a candidate for inclusion in Red Data Book in 1985. Locally common to abundant, with populations apparently stable throughout range; occurrence sporadic in W Kenya, the E extremity of range. No further information available on abundance. Not considered threatened anywhere.

Bibliography. Bannerman (1953), Bates (1930), Britton (1980), Brown & Britton (1980), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1963), Jackson (1910), Jackson & Selaier (1938), Komen (1991b), Lewis & Pomeroy (1989), Louette (1981), Mackworth-Praed & Grant (1957, 1970), Urban *et al.* (1986).

29. Finsch's Francolin

Francolinus finschi

French: Francolin de Finsch German: Finschfrankolin Spanish: Francolin de Finsch

Taxonomy. *Francolinus Finschi* Bocage, 1881, Caconda, Benguela, Angola.

Forms superspecies with *F. streptophorus*, *F. levaillantii* and *F. africanus*. Recently proposed reorganization of *Francolinus* places present species in genus *Sclerophila* with *F. streptophorus*, *F. levaillantii*, *F. africanus*, *F. psilolaemus*, *F. shelleyi* and *F. levaillantoides*. Monotypic.

Distribution. Found in three areas: lower R Congo in Congo and Zaïre; Kwando Province, S Zaïre; and WC Angola.

Descriptive notes. c. 35.5 cm; c. 560 g. Differs from other red-winged francolins by grey breast and lack of black and white pattern on face and neck.

Habitat. Woodland and grassland; at Gungu in S Zaïre occurs in grassland near gallery forest up to 600 m; on Mt Moco in Angola found on bare slopes above the tree-line at 2100 m; elsewhere in wooded savanna and also in *Brachystegia* woodland.

Food and Feeding. Beetles, insect larvae and seeds are taken. No further information available.

Breeding. Lays Jan, Mar, Jul in Zaïre and Jun-Jul in Angola. Probably monogamous. Nest hidden amongst vegetation on ground. Lays c. 5 eggs.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Currently considered near-threatened. Occurs in suitable habitat throughout an area of about 180,000 km². In Angola, sparsely distributed and uncommon to rare; in Zaïre reasonably common around Gungu; no information from lower R Congo. Nothing known about either actual or potential threats. A detailed assessment of the species' status is needed, especially regarding its occurrence in protected areas, and also of the efficiency of such areas in safeguarding the species.

Bibliography. Chapin (1946), Collar & Stuart (1985), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1960a, 1960b, 1963), Komen (1991b), Lippens & Wille (1976), Mackworth-Praed & Grant (1962, 1970), Pinto (1983), Snow (1978), Traylor (1963), Urban *et al.* (1986).

30. Red-winged Francolin

Francolinus levaillantii

French: Francolin de Levaillant German: Rotflügelfrankolin Spanish: Francolin Alirrojo

Taxonomy. *Perdix Levaillantii* Valenciennes, 1826, Cape of Good Hope.

Forms superspecies with *F. streptophorus*, *F. africanus* and *F. finschi*. Recently proposed reorganization of *Francolinus* places present species in genus *Sclerophila* with *F. streptophorus*, *F. finschi*, *F. africanus*, *F. psilolaemus*, *F. shelleyi* and *F. levaillantoides*. Population of N Malawi has been awarded separate race, *crawshayi*, but validity doubtful. Two subspecies recognized.

Subspecies and Distribution.

F. l. kikuyuensis Ogilvie-Grant, 1897 - Angola, Zambia, NE & E Zaïre E to WC Kenya.
F. l. levaillantii (Valenciennes, 1826) - N Malawi and NE Zambia S to E South Africa.

Descriptive notes. c. 33 cm; male 369-567 g, female 354-454 g. Differs from other red-winged francolins by ochre band on sides of throat and broad black and white gorget. Immature paler, with less distinct gorget. Race *kikuyuensis* distinguished by having less black in gorget, and by underpart coloration.

Habitat. Moist montane and upland grasslands, at 1800-3000 m in Kenya, preferring steep-sided valleys and damp areas. In Kivu, Zaïre, found in grass along watercourses, in brush and woodland, and amongst grass in clearings and fields.

Food and Feeding. Predominantly bulbs and

corns, especially of *Amayllidaceae* and *fridaceae*; small amounts of plant material taken from above ground; rest of diet made up of invertebrates, including ants, spiders and millipedes. More invertebrates consumed in summer, and bulbs and corns in winter.

Breeding. Lays in most months in S of range, Mar-Jul in E Cape Province and Aug-Feb in Natal, in E Africa Jan-Apr, Aug and Oct-Nov, depending on locality. Probably monogamous. Nest is a slight hollow lined with grass, leaves and similar, at base of cover. Usually 3-4 (mean 3.5) downy chicks are dark brown with some buff above, buffy below, and darker on breast.

Movements. Sedentary. Flies fair distances, but only when strongly pressed; is a good runner.
Status and Conservation. Not globally threatened. Mace-Land: Safe. Occurs in suitable habitat throughout area of nearly 1,000,000 km². Distribution is extremely patchy. Generally uncommon, but locally common; average density of 2-4 birds/km², but 10-20 birds/km² in good habitat in South Africa. Numbers within any given area generally believed to be stable, but habitats containing species retreating where habitat degraded through burning and overgrazing, or where afforested. Occurs in

Natal Drakensberg Park; effectively protected areas are likely to be important for long-term survival of species, at least in South Africa; main threat seems to be pressure on habitat.

Bibliography. Benson (1963), Benson & Benson (1975), Britton (1980), Clancey (1967), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Ginn *et al.* (1989), Hall (1963), Komen (1991b), Mackworth-Præd & Grant (1957-1973), Maclean (1993), Mentis (1973), Mentis & Bigalke (1973, 1979, 1980, 1981a, 1981b, 1985), Pinto (1983), Urban *et al.* (1986), Verheyen (1953).

31. Grey-winged Francolin

Francolinus africanus

French: Francolin à ailes grises **German:** Grauflügelfrankolin **Spanish:** Francolín Aligrís
Other common names: Greywing Francolin

Taxonomy. *Francolinus africanus* Stephens, 1819, Cape Province.

Forms superspecies with *F. streptophorus*, *F. levaillantii* and *F. finschi*. Recently proposed reorganization of *Francolinus* places present species in genus *Sclerophila* with *F. streptophorus*, *F. finschi*, *F. levaillantii*, *F. psilolaemus*, *F. shelleyi* and *F. levaillantoides*. *F. psilolaemus* has been included in present species. Monotypic.

Distribution. Lesotho and South Africa, from Cape Town E through Orange Free State and Natal to SE Transvaal.

Descriptive notes. 30-33 cm; male 345-539 g, female 354-369 g. Differs from other red-winged francolins by relatively small amount of chestnut in wings, narrow barring below and distinctive throat pattern. Immature duller with white throat.

Habitat. Montane grassland from about 1800 m to 2750 m in hills, occurring in patches of short grass and amongst small bushes; at sea-level in SW Cape Province, South Africa.

Food and Feeding. Predominantly bulbs and roots, especially of Amaryllidaceae, Cyperaceae and Iridaceae, for which digs with bill; small amounts of plant material taken from

above ground (e.g. fallen seeds and fruits); rest of diet made up of insects and other invertebrates, especially ants, beetles and grasshoppers in summer. Feeds in early morning and late afternoon.

Breeding. Lays Jul-Dec in Cape Province, Aug-Mar (peak Nov-Dec) in Natal, peak Oct-Dec in E Orange Free State; believed to begin earlier in E, S & W Cape, where rains are in winter, than Lesotho, Natal and extreme E Cape, where rains are in summer; gonadal development greatest during Jul-Dec in Natal and on Stormberg Plateau (E Cape). Monogamous and believed to be territorial. Nest is a slight hollow averaging 16.9 cm wide and 4.8 cm deep; lined with grass, leaves and occasionally feathers, at the base of a clump of grass. Usually 3-8 eggs (mean 5); incubation 21-22 days, by female only (male stays close by); downy chicks are mostly rufous brown and dark brown above, buffy below, washed rufous on breast. In summer rainfall area, longer breeding season may allow successful renesting, if first clutch fails. Hatching success 90%. Parents remain with chicks throughout the breeding season.

Movements. Sedentary. One covey in same area for 4 years.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout an area of c. 500,000 km². In general, locally distributed and uncommon, but abundant in optimal habitat; densities of 1-3 birds/km² in Natal Drakensberg, 6-11 birds/km² on Stormberg Plateau and in Lesotho; in good habitat throughout range 10-20 birds/km² reported; numbers stable. Main threats are anticipated loss of habitat to cultivation and forestry in some places, and habitat degradation and overexploitation for food in Lesotho. Known from Natal Drakensberg Park and Cape Point Nature Reserve. Subject of a commercially viable sustainable hunting industry, which advocates "wise use" for conservation; habitat and population managed to this end. Research has proposed sound management practices to conserve numbers; in summer rainfall areas, hunting should be limited to period from mid-Apr to end July, and in winter rainfall areas from early Apr to end June. Veld burning should stop in late Aug to allow birds to breed. Both hunted and non-hunted populations cyclical, with similar levels of genetic variation; increased immigration into hunted populations probably reduces effects of hunting on genetic structure.

Bibliography. Clancey (1957, 1967, 1986), Crowe & Crowe (1985), Crowe *et al.* (1992), Earle, Huchzermeyer *et al.* (1991), Earle, Little & Crowe (1992), Ginn *et al.* (1989), Grant & Little (1992a, 1992b), Grant *et al.* (1991), Hall (1963), Komen (1991b), Komen & Little (1992), Little (1992), Little & Crowe (1992a, 1992b, 1993a, 1993b), Little, Earle *et al.* (1993), Little, Gous & Crowe (1993), Little, Grant & Crowe, P.G. (1993), Little, Grant & Crowe, T.M. (1991, 1993), Little, Verster & Crowe (1993), Mackworth-Præd & Grant (1957), Maclean (1993), Mentis (1973), Mentis & Bigalke (1973, 1979, 1980, 1981a, 1981b, 1985), Mentis & Little (1992), Parker (1963), Urban *et al.* (1986).

32. Moorland Francolin

Francolinus psilolaemus

French: Francolin montagnard **German:** Hochlandfrankolin **Spanish:** Francolín Etíope
Other common names: Montane/Shoa Francolin; Elgon Francolin (*elgonensis*)

Taxonomy. *Francolinus psilolaemus* G. R. Gray, 1867, Shoa, Ethiopia.

Forms superspecies with *F. shelleyi* and *F. levaillantoides*. Recently proposed reorganization of *Francolinus* places present species in genus *Sclerophila* with *F. streptophorus*, *F. finschi*, *F. levaillantii*, *F. africanus*, *F. shelleyi* and *F. levaillantoides*. Has been considered conspecific with *F. africanus*. Other races have been described, but validity doubtful: *ellenbecki* included in nominate *psilolaemus*; and *theresae* in *elgonensis*. Race *elgonensis* has been considered separate species, or race of *F. shelleyi*. Two subspecies currently recognized.

Subspecies and Distribution.

F. p. psilolaemus G. R. Gray, 1867 - Ethiopia.

F. p. elgonensis Ogilvie-Grant, 1891 - E Uganda to C Kenya.

Descriptive notes. c. 32 cm, two males 510 g and 530 g, two females 370 g and 510 g. Only red-winged francolin with black bars at tips of primaries; S birds larger, with richer colouring on head and back. Race *psilolaemus* has throat and breast distinctively patterned; *elgonensis* has extensive rufous on underparts.

Habitat. Confined to montane *Erica* moorland and grassland at 1800-4000 m.

Food and Feeding. Diet undescribed; believed likely to be dominated by bulbs and roots.

Breeding. Apparently recorded laying in all months except Sept-Oct, but mostly Jan-Jun. Probably monogamous. One nest was situated in rough grass. Coveys of 4-5 young and adults regularly seen, size of coveys decreasing as year progresses.

Bibliography. Ash (1992), Britton (1980), Britton & Sugg (1973), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1963), Komen (1991b), Jackson & Sciater (1938), Lewis & Pomeroy (1989), Sessions (1967), Urban *et al.* (1986).

33. Shelley's Francolin

Francolinus shelleyi

French: Francolin de Shelley **German:** Shelleyfrankolin **Spanish:** Francolín de Shelley

Taxonomy. *Francolinus shelleyi* Ogilvie-Grant, 1890, Hartley Hills, Umfuli River, Zimbabwe. Forms superspecies with *F. psilolaemus* and *F. levaillantoides*. Recently proposed reorganization of *Francolinus* places present species in genus *Sclerophila* with *F. streptophorus*, *F. finschi*, *F. levaillantii*, *F. africanus*, *F. psilolaemus* and *F. levaillantoides*. Several other races have been described, but validity doubtful: *uluensis*, *canidorsalis* and *sequestris* all normally included within nominate *shelleyi*. Dubious race *uluensis* has alternatively been considered a race of *F. africanus*. Race *elgonensis* of *F. psilolaemus* has been considered to belong to present species. Two subspecies normally recognized.

Subspecies and Distribution.

F. s. shelleyi Ogilvie-Grant, 1890 - S Uganda and SW Kenya S through Tanzania, S Zambia, S Malawi, Zimbabwe and Mozambique to NE South Africa and Swaziland.

F. s. whytei Neumann, 1908 - SE Zaire, N Zambia and N Malawi.

Descriptive notes. c. 33 cm; 397-600 g. In flight, shows small rufous patch in wing. Characteristic blackish barring on underparts, especially on belly. Immature paler. Races vary in coloration: *shelleyi* darker, with distinctive bold pattern on underparts; *whytei* less heavily marked black and white on underparts, with buff throat.

Habitat. Occurs in variety of grassland and woodland habitats: open montane wooded savanna and grassland, thornveldt and clearings in woodland, e.g. *Brachystegia* and mopane; commonly in rocky and stony areas. Also amongst crops. From coastal areas in Mozambique and Natal up to 2200 m in Inyanga Highlands of Zimbabwe, and 2450 m on Nyika Plateau in Malawi; from 700 m to 3000 m in E Africa.

Food and Feeding. Varied diet, including roots and bulbs, fallen seeds, and invertebrates, such as small molluscs, termites and ants, grasshoppers and locusts.

Breeding. Lays during dry season, varying with locality, and recorded in most months: Aug-Jan in South Africa, Mar-Jul in E Africa. Probably monogamous. Nest is a slight hollow lined with grass, leaves and the like, well hidden amongst grass, herbs or rocks. Usually 4-5 eggs (4-7) in S Africa, 3-4 in Malawi; incubation 22 days; chicks have mostly rufous brown down above, buffy below. High predation rate among chicks.

Movements. Sedentary. Flies only when very pressed, preferring to sit tight or escape by running; flies only short distance.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Very widely distributed species occurring in suitable habitat throughout area of c. 1,300,000 km². Considered to be generally common, but is rare in some areas. No further information available on relative abundance. Known to retreat from areas degraded as consequence of overgrazing and continual burning. May not be in need of immediate attention, but much more detailed data required on relative abundance and actual or potential threats.

Bibliography. Benson (1963), Benson & Benson (1975), Britton (1980), Clancey (1967, 1977), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Ginn *et al.* (1989), Hall (1963), Hartley & Mundy (1992), Komen (1991b), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957-1973), Maclean (1993), Meyer (1971a), Urban *et al.* (1986), Vincent (1934).

34. Orange River Francolin

Francolinus levaillantoides

French: Francolin d'Archer **German:** Archerfrankolin **Spanish:** Francolín del Orange
Other common names: Archer's Francolin; Acacia/Ethiopian Francolin (*gutturalis/lori*)

Taxonomy. *Perdix levaillantoides* A. Smith, 1836, upper reaches of Orange River.

Forms superspecies with *F. psilolaemus* and *F. shelleyi*. Recently proposed reorganization of *Francolinus* places present species in genus *Sclerophila* with *F. streptophorus*, *F. finschi*, *F. levaillantii*, *F. africanus*, *F. psilolaemus* and *F. shelleyi*. Several other races have been described, but their validity is doubtful: *pallider* and *kalaharica* normally included in nominate *levaillantoides*; *cunensis* in *jugularis*; and *archeri* in *lori*. Race *gutturalis* (incorporating *lori*) has been considered to constitute a separate species. *F. garipeensis* is a synonym for present species. Four subspecies currently recognized.

Subspecies and Distribution.

F. l. gutturalis (Rüppell, 1835) - N Ethiopia.

F. l. lori Sharpe, 1897 - Sudan E through S Ethiopia to Somalia, and S to Uganda.

F. l. jugularis Büttikofer, 1889 - SW Angola and N Namibia.

F. l. levaillantoides (A. Smith, 1836) - E Namibia, S Botswana, N & W South Africa and Lesotho.

Descriptive notes. c. 32 cm; male 370-528 g, female 379-490 g. Large rufous patch in wing is visible in flight. Immature duller, barred below, lacks black collar. Races separated by intensity of ground colour and also of underpart markings.

Habitat. Occurs in wide range of grassland and woodland habitats, ranging from boulder strewn grassy mountain slopes with thorn scrub, through scrubby grassland to dry woodland.

Food and Feeding. Bulbs and corms, fallen seeds and fruits, and insects, such as bugs, grasshoppers and beetles.

Breeding. Lays in Feb-May and Sept-Oct in Transvaal; Jun in Namibia; Aug in Angola; and Feb, Apr and Aug in Ethiopia. Probably monogamous; territorial. Nest is a slight hollow under a grass clump. Usually 5-8 eggs.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Very widely distributed species occurring in suitable habitat throughout an area of c. 1,400,000 km². Frequent to common in Ethiopia and Somalia; formerly occurred in Djibouti. In South Africa only found in NW Cape Province, where probably numbers fewer than 500,000 individuals, and is thought to have declined during present century. In Namibia, numbers are stable and may be increasing. Possibly fairly common in Botswana; no information available from Angola, and no recent records from Lesotho. Occurs in Etosha Game Reserve and Daan Viljoen protected area in Namibia, but probably does not occur in any such reserve in South Africa; status in protected areas elsewhere not known; in Namibia these areas afford excellent protection, although species is widely distributed outside such reserves, and is unlikely to require protected areas for long-term survival. Main pressures are on habitat, with conversion to agricultural land and degradation through overgrazing. Species may not be in need of immediate attention, but more detailed data on abundance and actual or potential threats required. Two other fields of investigation merit consideration: research to provide a basis for protection and management; and promotion of sustainable sport hunting as a way of raising profile of Galliformes in Namibia, and providing an economic incentive for habitat conservation.

Bibliography. Ash (1992), Britton (1980), Brown & Britton (1980), Clancey (1967, 1986), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Ginn *et al.* (1989), Hall (1963), Komen (1991b), Lippens & Wille (1976), Mackworth-Præd & Grant (1957-1973), Maclean (1993), Parker (1963), Pinto (1983), Urban *et al.* (1986), Wolff (1978).

35. Scaly Francolin

Francolinus squamatus

French: Francolin écaillé German: Schuppenfrankolin Spanish: Francolín Escamoso

Taxonomy. *Francolinus squamatus* Cassin, 1857, Cape Lopez, Gabon.

Forms superspecies with *F. achantensis* and *F. griseostriatus*; these three species have been separated in genus *Squamotocolinus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Present species shows much internal variation and clinal extremes are sometimes accorded subspecific status, with up to seven different races having been proposed. Monotypic.

Distribution. Equatorial Africa between 10° N and 10° S: SC Nigeria SE to W Zaire and E to Uganda, S Sudan and SW Ethiopia, then S to E Zaire, NE Tanzania and extreme N Malawi; also recorded in C & S Zaire and WC Sudan.

Descriptive notes. c. 33 cm; male 372-565 g, female 377-515 g. A rather dark, heavily streaked species. Much variation, both locally and clinally; more mottled and blotched dorsally and paler ventrally in W than in E. Female tends to be smaller than male. Immature more rufous than female, with black markings.

Habitat. Evergreen forest with dense undergrowth from 800 m to 3000 m, including forest clearings; various secondary habitats, including plantations with dense undergrowth; found in small patches of forest and bush which have become quite isolated.

Food and Feeding. Fruits and seeds and a variety of crop plants, including sweet potatoes and groundnuts; also takes small insects, including termites and ants.

Breeding. Lays in all months except Feb in E Africa; lays Oct-Dec in Ethiopia and S Cameroon; Oct-Mar in W Cameroon; Jun-Aug in Gabon; Jan-Feb and May-Jun in Zaire. Probably monogamous. Nest is a slight hollow lined with grass, leaves and the like, under cover. Usually 6 eggs (3-8); downy chicks are mostly dark rufous brown above, buffy washed with rufous below. Chicks suffer heavy predation.

Movements. Sedentary. Prefers to sit tight rather than run if alarmed, but does fly up into trees.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Very widely distributed species occurring in suitable habitat throughout an area of c. 2,300,000 km². Common to abundant in Ethiopia; near Owerri, in Nigeria, it seems to be encountered c. 20 times more often than *F. bicalcaratus*. Widely distributed in most Ugandan forests, including a series of forest reserves and national parks. Main pressures are those affecting the forest habitat, but species is also trapped. Not in need of immediate attention, but more detailed data required on relative abundance and actual or potential threats.

Bibliography. Ash (1992), Bannerman (1930, 1953), Bates (1930), Benson (1963), Benson & Benson (1975), Britton (1980), Crowe (1993), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1963), Jackson & Selater (1938), Komen (1991b), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957-1973), Marchant (1957), Pinto (1983), Pomeroy & Abe (1992), Rodewald *et al.* (1994), Serle (1981), Sessions (1966), van Someren (1916), Urban *et al.* (1986).

36. Ahanta Francolin

Francolinus achantensis

French: Francolin d'Ahanta German: Ahantafrankolin Spanish: Francolín de Ahanta

Taxonomy. *Francolinus achantensis* Temminck, 1851, Ahanta, Ghana.

Forms superspecies with *F. squamatus* and *F. griseostriatus*; these three have been separated in genus *Squamotocolinus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. W populations have been awarded separate race, *happinsoni*, but variation is clinal and subspecific status not warranted. Monotypic.

Distribution. Occurs in three discrete areas in W Africa: W Senegal, Gambia, Guinea-Bissau and N Guinea; S Guinea, Sierra Leone and W Liberia; and NE Ivory Coast E to SW Nigeria.

Descriptive notes. c. 33 cm; male c. 608 g, female c. 487 g. Clinal variation, with paler, reddish brown wing-coverts to W. Female has darker secondaries. Immature has black arrow-shaped markings on mantle, scapulars and inner secondaries, underparts ashy.

Habitat. Edge and regrowth vegetation, such as forest edge, clearings and scrub between gallery forest and cultivation; thick undergrowth along watercourses and abandoned clearings. In Sierra Leone, most abundant in montane gallery forest; in Ghana, occurs in coastal thicket, and even recorded in teak plantation.

Food and Feeding. Varied diet, including seeds and small beans, cassava and large fruits, and insects.

Breeding. Little known. Lays in Jan and Sept in Senegambia; late Dec to Jan in Ghana and Sierra Leone. Nest is a scrape lined with leaves in cover. Usually 4-6 eggs (3-12); downy chicks have dark rufous brown upperparts, buffy with rufous wash below.

Movements. Sedentary. Flies only when very pressed, and then often perches in trees.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout range of c. 200,000 km². Candidate for inclusion in Red Data Book in 1985. Rare and local in Gambia and N Guinea-Bissau; widespread in both Sierra Leone and Ghana, and common in latter; probably widespread but at low densities and likely to be declining in Ivory Coast; common in E of range. Occurs in Tai National Park, but much of this is unsuitable habitat, so species restricted to edge and regrowth areas in park. In Ivory Coast at least, threatened by conversion of habitat for agriculture and by overhunting for food; hunting has been somewhat reduced in Tai National Park. Not believed to be in need of immediate attention but more detailed data required on abundance and actual or potential threats.

Bibliography. Bannerman (1930, 1935, 1953), Collier (1935), Colston & Curry-Lindahl (1986), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Elgoud (1982), Grimes (1987), Hall (1963), Holman (1947), Komen (1991b), Mackworth-Præd & Grant (1970), Urban *et al.* (1986), White (1965).

37. Grey-striped Francolin

Francolinus griseostriatus

French: Francolin à bandes grises German: Graustreifenfrankolin Spanish: Francolín Angoleño

Taxonomy. *Francolinus griseo-striatus* Ogilvie-Grant, 1890, Quanza River, northern Angola.

Forms superspecies with *F. achantensis* and *F. squamatus*; these three have been separated in genus *Squamotocolinus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Monotypic.

Distribution. Two disjunct populations in W Angola: S Cuanza and W Milanje; and S Benguela and extreme NE Huila.

Descriptive notes. c. 33 cm; male c. 430 g, female c. 390 g. Differs from other "scaly" francolins by rufous chestnut streaky breast, mantle and upperwing-coverts. Spurs lacking or rudimentary in female. Immature has black markings all over, with richer upperparts and paler underparts.

Habitat. Gallery forest and secondary forest in dense understorey, and dense thickets; occurs from 800 m up to 1200 m.

Food and Feeding. Not well documented; small arthropods, shoots and seeds. Feeds in grass and abandoned cotton fields next to forest in early morning and late afternoon.

Breeding. No information available.

Movements. Sedentary. Moves out from forest to feed in early morning and late afternoon. If alarmed, flies back to forest.

Status and Conservation. Not globally threatened. Mace-Lande: Insufficient information. Currently considered near-threatened. Status unknown and species not recorded since 1954; most records are of specimens collected before 1910. Civil strife currently widespread throughout known range. Possible presence of species in protected areas unknown; occurs in Angola Endemic Bird Area. No threats identified, due to general lack of data; forest destruction may be a problem. Extensive survey urgently needed to assess status and recommend future actions, but military situation currently precludes this.

Bibliography. Collier & Slogar (1985), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1960b, 1963), Heinrich (1958), Komen (1991b), Mackworth-Præd & Grant (1962), Pinto (1970, 1983), Urban *et al.* (1986).

38. Nahan's Francolin

Francolinus nahani

French: Francolin de Nahan German: Nahanfrankolin Spanish: Francolín de Nahan
Other common names: Nahan's Forest Francolin

Taxonomy. *Francolinus nahani* Dubois, 1905, Popoie, Aruwimi River, Zaïre. Formerly placed in monotypic genus *Acentorhynchus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Monotypic.
Distribution. NE Zaïre (area bordered by R Aruwimi, R Nepoko and R Semliki) and W & SC Uganda (forests of Budongo, Bugoma and Mabira).

Descriptive notes. 23-26 cm; two males 308 g and 312 g, three females 234-260 g. Unspurred; distinctive combination of bare red skin around eyes, mostly white throat and black and white remainder of underparts. Immature darker, with grey legs.
Habitat. Inhabits dense primary forest up to altitude of 1400 m.
Food and Feeding. Varied diet, including invertebrates (insects and small molluscs), shoots, seeds and bulbs. Scratches leaf litter to find food. Specimens have been obtained by baiting with grain.
Breeding. Believed to breed throughout year.

Probably monogamous. Only known nest was in tree hollow, 1 m above ground; clutch of 4 eggs.
Movements. Sedentary.

Status and Conservation. RARE. Mace-Lande: Insufficient information. Very poorly known, with little recent information. Presumed to be declining due to loss of habitat and hunting. Occurs in Bugoma, Kibale and Mabira Forest Reserves; population in Semliki Valley is within Virunga National Park, and would be best protected by extension of this park to include E Ituri Forest. Loss of tree cover due to timber extraction and overexploitation for food are possible threats. An extensive survey is needed in order to permit assessment of the species' status in both Uganda and Zaïre.

Bibliography. Britton (1980), Chapin (1926, 1932), Collar & Andrew (1988), Collar & Stuart (1985), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Dubois (1905), Friedman (1966), Friedman & Williams (1973), Hall (1963), Jackson & Selater (1938), Komen (1991b), Lippens & Wille (1976), Mackworth-Præd & Grant (1957, 1970), Schoueden (1918, 1963, 1968), van Someren (1916, 1918, 1922, 1926), Urban *et al.* (1986).

39. Hartlaub's Francolin

Francolinus hartlaubi

French: Francolin de Hartlaub German: Hartlaubfrankolin Spanish: Francolín de Hartlaub

Taxonomy. *Francolinus Hartlaubi* Bocage, 1869, Huila, southern Angola.

Has been included in genus *Chaetopus*, or separated in monotypic genus *Chapinortyx*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Monotypic.

Distribution. SW Angola (from Benguela) S to C Namibia around Tropic of Capricorn.

Descriptive notes. Male c. 28 cm, 245-290 g; female c. 25 cm, 210-240 g. Male differs from similar species in head and underpart coloration. Female very different, with distinctive greyish neck and pale cinnamon brown underparts. Some geographical variation, with birds at centre of range darker than those to N and S. Immature male paler above than adult male, with narrower streaks below; immature female similar to adult female.
Habitat. Hills, kopjes, ridges and mounds covered with scrub, bushes and grasses on a sandy soil.
Food and Feeding. Berries, bulbs and seeds;

also invertebrates, including small snails and insects.

Breeding. Apr-Aug in Namibia, also Nov and Feb; season possibly varies with rainfall. Monogamous and territorial. Only 1 nest described, in hollow on cliff ledge. Clutch probably 4-8 eggs. Family parties seen for some months after hatching.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout a range of c. 300,000 km². Considered a candidate for inclusion in Red Data Book in 1985. Believed rare and locally distributed in a restricted habitat type; possibly stable overall, but numbers may be declining in Namibia; no recent information from Angola. Known from Waterburg Plateau and Daan Viljoen Parks in Namibia, and Iona National Park in Huila, Angola; Waterburg, at least, provides effective protection, and these and any other protected areas may become very important in the long-term conservation of present species. As it occurs on granitic hills, it is suffering from consequences of granite extraction in some areas. Not believed to be in need of immediate attention but much more detailed data on relative abundance and actual or potential threats required.

Bibliography. Clancey (1967, 1986), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Ginn *et al.* (1989), Hall (1963), Komen (1986, 1987, 1990, 1991b), Komen & Little (1992), Komen & Meyer (1984), MacDonald (1957), Mackworth-Præd & Grant (1962), Maclean (1993), Pinto (1983), Urban *et al.* (1986).

40. Double-spurred Francolin

Francolinus bicalcaratus

French: Francolin à double éperon German: Doppelspornfrankolin Spanish: Francolín Biespolado

Taxonomy. *Tetrao bicalcaratus* Linnaeus, 1766, Senegal.

Forms superspecies with *F. clappertoni*, *F. icterorhynchus* and *F. harwoodi*. Has been included in genus *Chaetopus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Several races proposed, but these are simply examples of both local and clinal variation within nominate *bicalcaratus*. Two subspecies recognized.

Subspecies and Distribution.

F. b. ayesha Hartert, 1917 - W Morocco, from Rabat to Mogador.

F. b. bicalcaratus (Linnaeus, 1766) - Senegambia E to SW Chad and W Central African Republic

Descriptive notes. 30-34 cm; male c. 507 g, female c. 381 g; wingspan 45-50 cm. Differs from similar francolins by leg colour and lack of bare skin around eye. Female averages smaller, with much reduced spurs. Immature duller and more heavily barred. Birds in S and E of range are darker; race *ayesha* larger, paler above and with less chestnut below.

Habitat. Wide variety of open habitats from moist savanna to arid savanna and from *Cistus* heath to woodland; man-made habitats, such as farmland, pastures and abandoned cultivation. Seldom far from human habitation. In Morocco, occurs in moister Mediterranean

vegetation in lowlands of Atlantic coast; mainly in forest or woodland fringes. Not far from water.
Food and Feeding. In W Africa is opportunist, diet varying somewhat with habitat. Mostly plant matter, such as fruit, roots and green leaves and some crop seeds (millet, groundnuts, etc.); also frogs, small molluscs, termites, caterpillars and other insects and their larvae. Feeds mainly in early morning and late afternoon, but throughout day during rainy season.

Breeding. Lays in all months according to locality; thought to be May in Morocco (*ayesha*); in Senegambia and E of range, Jan-May and Aug-Dec where water present, otherwise during rains; Sept-Mar in Sierra Leone; Aug-Feb in Ivory Coast; in Mali, all months in S, Aug-Oct in Sahel; Sept in Niger; Oct and Feb in Benin; Sept-Mar in Nigeria; Oct-Dec in S Cameroon. Probably monogamous. Nest is a hollow occasionally lined with grass, leaves and similar material, at base of cover. Usually 6 eggs (5-7); downy chicks have broad dark rufous brown central stripe above, creamy buff underparts. Average 70% of chicks survive to fledging.

Movements. Sedentary. Active in early morning and late afternoon, moving into shade during hottest part of day. Flies strongly 4-5 m above ground for less than 200 m, but only when strongly pressed; prefers to run away.

Status and Conservation. Not globally threatened. Mace-Lande: *bicalcaratus* safe; *ayesha* endangered. Nominative *bicalcaratus* considered commonest W African non-forest francolin in mid-1980's; ranges from common in Gambia, to abundant in Sierra Leone and locally in Ghana. Race *ayesha* treated separately because of very small, isolated distribution: one known and one possible location, Sidi Bettache and Moulay Bouazza respectively; in 1970's birds heard calling at Sidi Bettache only, despite intensive searches in Forest of Mamora too; Sidi Bettache is protected. This race considered a cause for concern, but detailed information lacking; believed to have increased in number between 1982 and 1988, with at most a few hundred birds in 1988; current status unknown; believed to be threatened by habitat degradation and overexploitation for food. Nominative *bicalcaratus* overhunted outside protected areas in Ivory Coast. Extensive surveys should aim to identify other areas with potential for protection, and research to guide management would be beneficial, as would monitoring of known populations.

Bibliography. Akande (1977), Bannerman (1930, 1953, 1957), Bates (1930), Cramp & Simmons (1980), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Etchécopar & Hue (1964), Fairbairn (1952), Ginn (1987), Hall (1963), Heim de Balsac & Mayaud (1962), Heinze & Knott (1979), Hollom *et al.* (1988), Hopkinson (1923), Komen (1991b), Mackworth-Præd & Grant (1970), de la Perche (1992), Thiollay (1970), Urban *et al.* (1986), Walls (1933).

41. Heuglin's Francolin

Francolinus icterorhynchus

French: Francolin à bec jaune German: Gelbschnabelfrankolin Spanish: Francolín Piquigualdo

Other common names: Yellow-billed Francolin

Taxonomy. *Francolinus icterorhynchus* Heuglin, 1863, Bongo River, Bahr-el-Ghuzal, Sudan.

Forms superspecies with *F. clappertoni*, *F. bicalcaratus* and *F. harwoodi*.

Has been included in genus *Chaetopus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Proposed race *dybowskii* is an example of clinal variation and does not merit subspecific status. Monotypic.

Distribution. Central African Republic, S Sudan, N Zaïre and W Uganda.

Descriptive notes. c. 32 cm; male 504-588 g, female 420-462 g. Differs from *F. bicalcaratus* by peculiar markings below and by having bill and legs yellow to orange, rather than greenish; from *F. clappertoni* by yellow, not red, bare parts. Female averages smaller, with much reduced spurs. Immature has more distinct barring on upperparts. Birds in E are darker.

Habitat. Open habitats between 500 m and 1400 m, ranging from grassland to savanna with scattered tree cover; also in cultivation.
Food and Feeding. Varied diet includes seeds and berries, millipedes, beetles and termites.
Breeding. Lays in Feb, Apr-Jul and Oct in

Uganda, apparently unrelated to rains; Sept-Nov in Zaïre, during late rainy season. Probably monogamous. Nest is a scrape in ground, in cover. Usually 6-8 eggs; downy chicks have broad rufous brown and dark brown central stripe above, buffy underparts.

Movements. Sedentary. Flies up to perches only when very pressed, preferring to escape by running into cover.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Widely distributed, occurring in suitable habitat throughout a range of about 1,400,000 km². Common to abundant in most parts of range. Not in need of conservation attention.

Bibliography Britton (1980), Brown & Britton (1980), Chapin (1932), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1963), Jackson & Sclater (1938), Komen (1991b), Lippens & Wille (1976), Mackworth-Præd & Grant (1970), Nikolaus (1987), Urban *et al.* (1986), White (1965).

42. Clapperton's Francolin *Francolinus clappertoni*

French: Francolin de Clapperton **Spanish:** Francolín de Clapperton
German: Clappertonfrankolin

Taxonomy. *Francolinus Clappertoni* Children, 1826, no locality = Bornu. Forms superspecies with *F. icterorhynchus*, *F. bicalcaratus* and *F. harwoodi*. Has been included in genus *Chaetopus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Various races proposed, including *sharpii*, *konigseggii* and *nigrosquamatus*, but geographical variation in plumage is complex and validity of races is dubious. Monotypic.

Distribution. E Mali (from Azzawak) E through C Niger, NE Nigeria, N Cameroon, S Chad and S & C Sudan to N Uganda and Ethiopia.

Descriptive notes. c. 32 cm; male c. 604 g, female c. 463 g. Differs from *F. icterorhynchus*, *F. hildebrandti* and *F. bicalcaratus* by red patch around eye; white throat and fore-neck also distinctive. Much variation in extent of moustachial stripe and of brown markings below. Female averages smaller, with much reduced spurs. Immature less distinctly marked.

Habitat. Semi-arid savanna, open savanna woodland and especially sandy grassland, including that of *Hyparrhenia*, with trees and bushes, e.g. *Acacia*, *Terminalia*, *Combretum*; occurs up to 2300 m; also in cultivation and

on rocky hillsides.

Food and Feeding. Seeds and berries, small molluscs and insects.

Breeding. Lays Aug-Sept in Mali and Sudan; Jul-Sept in Chad; Feb-Mar in Nigeria; Feb and Apr-Dec in Ethiopia. Probably monogamous. Nest is a well hidden hollow on ground. Clutch size unknown; maximum of 4 young seen with adult.

Movements. Sedentary. Often active in late afternoon.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Patchily distributed in suitable habitat within a large range of c. 2,000,000 km². Generally locally common to abundant, e.g. common in Waza and Kalamaloué National Parks, N Cameroon. Decreasing in some areas, at least in Ethiopia, e.g. Rift Valley, due to degradation of habitat and its conversion for agriculture; overhunting is also problem in some areas. Not in need of conservation attention.

Bibliography Ash (1992), Bannerman (1953), Britton (1980), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1963), Komen (1991b), Mackworth-Præd & Grant (1957, 1970), Nikolaus (1987), Salvan (1978), Urban *et al.* (1986).

43. Harwood's Francolin *Francolinus harwoodi*

French: Francolin de Harwood **German:** Harwoodfrankolin **Spanish:** Francolín de Harwood

Taxonomy. *Francolinus harwoodi* Blundell and Lovat, 1899, Aheafeg, Shoa, Ethiopia. Forms superspecies with *F. icterorhynchus*, *F. bicalcaratus* and *F. clappertoni*. Has been included in genus *Chaetopus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Monotypic.

Distribution. Very small range in highlands of C Ethiopia around R Blue Nile and its tributaries, occurring locally at and around Aheafeg, Jemmu Valley, Kalo Ford, R Muger and a few other sites.

Descriptive notes. c. 33 cm; one male 545 g, one female 446 g. Differs from *F. natalensis* by head pattern and more black and buff underparts. Female has slightly paler, browner underparts, with spurs much reduced.

Habitat. Large, dense *Typha* beds with scattered trees, along small, shallow watercourses; feeds in adjacent sorghum fields. Possibly also *Terminalia/Combretum* woodland with tall *Hyparrhenia* grass.

Food and Feeding. Tubers, possibly those of *Dioscorea*; seeds, including those of the grass *Echinochloa*; berries, including *Amaranthus*; sorghum; and fruit; also termites.

Breeding. Only information is a brood of 3, about 5 weeks old, seen in mid-Feb; first egg probably laid in early to mid-Dec.

Movements. Sedentary. Moves out into sorghum fields to feed; if alarmed, flies back into reedbeds.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Currently considered near-threatened. Little known, but considered locally common in suitable habitat within c. 50,000 km². Restricted range; occurs in Central Ethiopian Highlands Endemic Bird Area. Status requires clarification: as species is Ethiopian endemic, its habitat is likely to be under pressure from expanding human population; species may be trapped in increasing numbers, as reported to be excellent food. Not reckoned to need immediate attention, but more detailed data required on abundance and actual or potential threats.

Bibliography Ash (1978, 1992), Ash & Gullick (1989), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1963), Komen (1991b), Mackworth-Præd & Grant (1957), Urban (1980), Urban *et al.* (1986).

44. Red-billed Francolin *Francolinus adspersus*

French: Francolin à bec rouge **German:** Rotschnabelfrankolin **Spanish:** Francolín Piquirrojo

Taxonomy. *Francolinus adspersus* Waterhouse, 1838, Great Fish River, Great Namaqualand.

Has been included in genus *Notocolinus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Monotypic.

Distribution. S Angola S through Namibia to extreme N South Africa; S Zambia, W Zimbabwe, Botswana.

Probably introduced successfully to Hawaii.

Descriptive notes. Male c. 38 cm, 340-635 g; female c. 33 cm, 340-549 g. Shows rather conspicuous and very distinctive yellow eye-ringing and finely barred underparts. Female averages smaller than male, with much reduced spurs. Immature much browner with buff bars and streaks.

Habitat. Arid savanna and floodplains; *Baikaiea*, *Acacia* and mixed woodlands, brush country and thickets, often near water.

Food and Feeding. Green parts of plants, berries and bulbs, and termites, beetles, grasshoppers and bugs; in Zambia known to eat seeds of the tree *Guibouria coleosperma*, and in

Namibia fruits of devil thorn (*Tribulus terrestris*).

Breeding. Breeds in late rains or early dry season; mainly Dec-Apr, but any month, in C & S Namibia; mainly Apr-Jun in N Namibia and Botswana; May in Zambia; Jan-Mar, May, and Jul-Aug in Zimbabwe. Probably monogamous. Nest is a hollow under a bush. Lays 4-10 eggs; incubation 22 days (in captivity); downy chicks have broad dark brown central stripe above, pale yellowish buff below, with darker breast; adult plumage attained at c. 3 months, spurs evident at c. 5 months.

Movements. Sedentary; occurs at higher altitudes during floods. Active in early morning and late afternoon, moving to shade during the heat of the day. Flies only when strongly pressed, preferring to escape by running, but will fly up into trees.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout c. 700,000 km². Considered widespread and abundant in Namibia, where numbers are stable; occurs in most protected areas in the country, although its survival is not likely to depend upon such areas. In Zimbabwe, only occurs in NW, much of which is protected or safari land where hunting is permitted and a Dec-Mar shooting season is recommended. Not in need of conservation attention; sport hunting may be considered as a means of raising funds for protection of both species and habitat.

Bibliography Benson (1963), Clancey (1967, 1986), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Ginn *et al.* (1989), Hall (1963), Hartley & Mundy (1992), Komen (1991b), Komen & Little (1992), Mackworth-Præd & Grant (1962), Maclean (1993), Mallet (1964), Pinto (1983), Urban *et al.* (1986).

45. Cape Francolin *Francolinus capensis*

French: Francolin criard **German:** Kapfrankolin **Spanish:** Francolín de El Cabo

Taxonomy. *Tetrao capensis* Gmelin, 1789, Cape of Good Hope.

Has been included in genus *Notocolinus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Monotypic.

Distribution. South Africa, in S & W Cape Province from Cape Peninsula E to E Cape; presence on lower Orange R currently considered doubtful.

Descriptive notes. 40-43 cm; male 600-915 g, female 435-659 g. Rather dark overall, with distinctive pattern of white streaks and vermiculations. Female averages smaller, and has legs dull orange, not orange-red, with much reduced spurs. Immature browner above, greyer below with less distinct markings.

Habitat. Inhabits scrub vegetation including scrubby heath, fynbos and sheltered riverine scrub. Also exotic *Acacia* stands; will venture onto garden lawns where not persecuted.

Food and Feeding. Bulbs and coms, seeds, berries and shoots; also small molluscs, termites, ants and other insects.

Breeding. Lays Jul-Feb, with peak in Sept-Oct, late in winter rains or early in dry summer. Probably monogamous. Nest is a hollow lined with grass, well hidden under cover. Usually 6-8 eggs (mean of 25 clutches, 7-4); mean size of 45 broods was 4-2 chicks.

Movements. Sedentary. Flies only when hard pressed, preferring to escape by running.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout c. 185,000 km². Locally common; numbers believed to be stable. Occurs in Cape Point and De Hoop Nature Reserves, which offer some protection, but are too small; whilst designation of further protected areas would be of benefit, such areas are probably not essential for long-term survival of species. Agricultural intensification may be a problem, as might overhunting.

Bibliography Clancey (1967, 1986), Crowe (1993), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Ginn *et al.* (1989), Hall (1963), Heyl (1988a, 1988b), Komen (1986, 1991b), Mackworth-Præd & Grant (1962), Maclean (1993), Schönwetter (1967), Urban *et al.* (1986).

46. Natal Francolin *Francolinus natalensis*

French: Francolin du Natal **German:** Natalfrankolin **Spanish:** Francolín de Natal

Taxonomy. *Francolinus Natalensis* A. Smith, 1834, Durban, Natal.

Forms superspecies with *F. hildebrandti*, with which occasional hybridization has been reported. Has at times been placed in genus *Chaetopus*, or alternatively in *Notocolinus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Races proposed at various times, such as *neavei*, but variation clinal and validity of races not supported. Hybridizes with *F. swainsoni* in W Zimbabwe. Monotypic.

Distribution. C Zambia S through Zimbabwe and Swaziland to E South Africa (W Orange Free State, Natal, N & E Cape Province).

Descriptive notes. 30-38 cm; male 415-723 g, female 370-482 g. Differs from very similar male *F. hildebrandti* by finer, more regular black markings on underparts; from male *F. hartlaubi* by

red bill and feet; and from *F. clappertoni* by lack of distinct white supercilium. Female averages smaller, with much reduced spurs. Immature paler; underparts buff finely barred black, with white shaft streaks. Much geographical variation, with characters varying independently of each other: birds at centre of range paler than those to N and S.

Habitat. Usually occurs in habitats with some cover up to 1800 m, including hillsides littered with dense thickets, dry forest along water-courses and bush or woodland with undergrowth; even montane forest and bush. Also *Acacia* scrub in rocky country; amongst vegetation along rivers; and amidst mature crops on farmland.

Food and Feeding. Small bulbs and roots, cowpeas, berries and seeds, including grain; also beetles, termites, grasshoppers and caterpillars. Forages on rhinoceros and elephant dung.

Breeding. Probably breeds in late rains and winter across range as a whole; nesting unpredictable, usually Jan-Feb and Apr-Jul in South Africa; all months except Oct, especially Mar-May (over 50% of clutches) in Zimbabwe; Mar-May in Zambia. Probably monogamous. Nest is a scrape lined with grass in heavy cover. Usually 5 eggs (2-8); incubation in captivity 20 days, by female only; downy chicks have broad rufous brown central stripe above, creamy buff underparts.

Movements. Sedentary. Active early morning and late afternoon, moving to cover during midday heat. Slow flier, preferring to land in cover to evade raptors.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout area of over 1,000,000 km². Considered generally abundant, locally common. In South Africa, numbers have declined due to land development, but are now considered stable, and sport hunting provides commercial incentive to conserve species: species occurs in several protected areas although its survival is not likely to depend upon such areas. In Zimbabwe, where hunting is permitted, a Aug-Nov shooting season is recommended. Not in need of conservation attention.

Bibliography. Benson (1963), Clancey (1967, 1986), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Ginn *et al.* (1989), Hall (1963), Harrap (1964), Hartley & Mundy (1992), Irwin (1971), Komen (1991b), Mackworth-Praed & Grant (1962), Maclean (1993), Urban *et al.* (1986).

47. Hildebrandt's Francolin

Francolinus hildebrandti

French: Francolin de Hildebrandt

Spanish: Francolín de Hildebrandt

German: Hildebrandtfrankolin

Taxonomy. *Francolinus hildebrandti* Cabanis, 1878, Voi, Taita district, Kenya.

Forms superspecies with *F. natalensis*, with which occasional hybridization has been reported. Has at times been placed in genus *Chaetopus*, or alternatively in *Notocolinus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Proposed races, such as *johnstonii*, not valid, as variation is clinal. Monotypic.

Distribution. C & W Kenya S through Tanzania to SE Zaire (Musosa), NE Zambia and Malawi.

Descriptive notes. c. 34 cm; two males 600 g and 645 g, 2 females 430 g and 480 g. Male differs from very similar *F. natalensis* by less regularly patterned, more blotched underparts. Female has very distinctive rufous-buff underparts; in S of range, smaller and lacks white streaking on mantle. Immature more distinctly barred above than female.

Habitat. Open habitats with scattered cover between 2000 m and 2500 m; on rocky hillsides with dense scrub, thickets and bush grassland; low heath at higher altitudes.

Food and Feeding. Bulbs, tubers and seeds; also insects and their larvae.

Breeding. Lays in most months according to locality: Jul in Zambia; Apr-Nov (peak Jun-Jul) in Malawi; Jan, Mar, May-Aug and Nov-Dec in E Africa, apparently unrelated to rainfall. Probably monogamous. Nest is a well concealed scrape, lined with grass and leaves. Usually 6 eggs (4-8); downy chicks have broad rufous brown central stripe above, and buffy underparts.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout c. 1,200,000 km². In general, very locally distributed and uncommon. No further information available. Not considered to be in need of conservation attention, but detailed information on status and local abundance required.

Bibliography. Benson & Benson (1975), Britton (1980), Brown & Britton (1980), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1963), Jackson & Selator (1938), Komen (1991b), Lewis & Pomeroy (1989), Lippens & Wille (1976), Mackworth-Praed & Grant (1957-1973), Pomeroy & Abe (1992), Urban *et al.* (1986), Vincent (1934).

48. Yellow-necked Francolin

Francolinus leucoscepus

French: Francolin à cou jaune

German: Gelbkehlfrankolin

Spanish: Francolín Gorgiamarillo

Other common names: Yellow-necked Spurfwol

Taxonomy. *Francolinus leucoscepus* G. R. Gray, 1867, Ethiopia.

Forms superspecies with *F. rufopictus*, *F. afer* and *F. swainsonii*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Various races proposed, but variation clinal and validity dubious; *infusatus* sometimes accepted. Hybridizes with *F. rufopictus* on edge of range in Tanzania. Monotypic.

Distribution. SE Sudan E through Ethiopia to Somalia, and S to NE Uganda, C Kenya and NC Tanzania.

Descriptive notes. c. 35 cm; male 615-896 g, female 400-615 g. Large francolin with orange-red bare skin around eye. Only francolin with bare yellow skin on throat and foreneck; large buff patch in primaries conspicuous in flight, black bill. Female averages smaller and has shorter spurs. Immature less distinctly marked.

Habitat. Inhabits both natural habitats and those altered by man, appearing to prefer *Acacia/Commiphora* bush with mixed annual and perennial grasses, and typically 200-400 mm of rain per year. Believed to be reasonably adaptable, and occurs in cultivation, including that sited in woodland, but only where human population fairly sparse.

Food and Feeding. In S Kenya and Tanzania, feeds predominantly on sedge tubers, especially *Cyperus rotundus*, which constitute over 50% by volume over year; fruits and seeds of herbs and grasses, mainly *Commelina*, *Cruciferae* and *Dryopteris*, 12.7% by volume over year; wide range of other plant matter of nearly 30 species, primarily seeds, amounting to 16.2%; also insects, 18.8%, mainly termites, 17.5%. During dry season, sedge tubers are main food, but these possibly drop to 7-18% by volume after rain, when grass and herb seeds become more important, and insects even more so until seeds have set. May also feed on fallen grain and legume crops around harvest time. Scratches loose ground with feet and eats food items exposed.

Breeding. Breeds late in rains if possible, so that hatching is in cool dry season. Nesting mainly May-Jul in Kenya and N Tanzania, but recorded in every month except Feb: Jan-Jun in Ethiopia; mainly Apr-Jun in Somalia. Monogamous and territorial during breeding season; rains are likely to stimulate breeding activity. Nest is a scrape, sometimes lined with grass, feathers, etc. In areas and times of low rainfall only a few pairs may form and no breeding may take place. Usually 5 eggs (3-8); incubation 18-20 days; downy chicks have dark brown broad central stripe above, buffy underparts. Chicks leave nest at c. 24 hours and stay with parents until adult size; at 4-6 weeks full set of juvenile primaries complete; spurs erupt around 18th week. Where there are two rainy seasons, family groups split at onset of following rains; where only 1 rainy season, may remain together until next breeding season. Many broods fail: average 4-3 chicks remain at 10-14 weeks; survival to adulthood probably less than 2 birds/pair/year.

Movements. Sedentary. In early morning may walk or fly hundreds of metres to particular areas, e.g. of crops, to feed. Follows elephants and rhinoceroses to forage on fresh droppings. When alarmed runs or flies to cover.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout area of over 1,300,000 km². Considered frequent overall, but is common in some areas; in Kenya, densities of 81 birds/km² and 78 birds/km² recorded in suitable habitat at Selengei and Oluturo respectively, down to 2 birds/km² in wooded brushland; now extinct in extensive tracts of the country. Frequent to common in Ethiopia and Somalia. Numbers generally higher in cultivation; species can tolerate some human settlements, but retreats from densely populated areas. Decline in Kenya partly due to use of nylon in making snares for trapping; species easily trapped at edges of cultivation. Not in need of conservation attention, but extent of local extinctions should be monitored.

Bibliography. Archer & Godman (1937), Ash (1992), Ash & Mskell (1983), Britton (1980), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1963), Jackson & Selator (1938), Komen (1991b), Lack (1985), Lack *et al.* (1980), Lewis & Pomeroy (1989), Mackworth-Praed & Grant (1957), Pomeroy & Abe (1992), Redhead (1972), Snow (1978), Stronach (1966), Swank (1977), Urban *et al.* (1986).

49. Grey-breasted Francolin

Francolinus rufopictus

French: Francolin à poitrine grise

Spanish: Francolín del Victoria

German: Graubrustfrankolin

Other common names: Grey-breasted Spurfwol

Taxonomy. *Pternistis rufopictus* Reichenow, 1887, Wembere Steppe, Tanzania.

Forms superspecies with *F. leucoscepus*, *F. afer* and *F. swainsonii*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Local hybridization with *F. leucoscepus* has been reported. Monotypic.

Distribution. NW Tanzania, from L. Victoria to Serengeti and S to Wembere.

Descriptive notes. c. 35 cm; male 779-964 g, female 439-666 g. Differs from *F. leucoscepus* in reddish orange bill and bare skin on throat, and by chestnut on upperparts; from *F. afer* by black legs and generally paler plumage. Female averages smaller and has much shorter spurs. Immature much greyer above; underparts barred black and white.

Habitat. Inhabits plains and savannas in areas with rainfall of 500-700 mm, including edge of grassland and *Aeneia* woodland of, e.g. *A. tortilis*, *A. drepanolobium*, *A. xanthophylla* and *A. kirkii*; also in thickets along water-courses.

Food and Feeding. Feeds predominantly on predominantly *Cyperus* sedge tubers; also seeds and insects, e.g. grasshoppers and termites. Digs for tubers and also forages on seeds of weeds, legumes and cereals on farmland.

Breeding. Lays during late rains and dry season, in Feb-Apr and Jun-Jul. Monogamous and territorial. Nest is a depression amongst long grass, lined with grass and feathers. Usually 4-5 eggs; downy chicks have dark brown broad central stripe above, buffy underparts. Family groups usually number less than 7 individuals. Young remain with parents until following breeding season.

Movements. Sedentary. Moves into open to feed only in early morning and late afternoon.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout c. 30,000 km². Considered a candidate for inclusion in Red Data Book in 1985. Restricted range; occurs in Serengeti Endemic Bird Area. Generally considered common, but only frequent in some areas. In St. Serengeti National Park hybridizes with *F. leucoscepus*, resulting in human population expands, causing concomitant spread from W into interior, and domestic stock grazing. Not believed to be in need of conservation attention, but detailed information should be gathered on status and abundance.

Bibliography. Britton (1980), Brown & Britton (1980), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1963), Komen (1991b), Mackworth-Praed & Grant (1957), Schmidt (1982), Turner (1977), Urban *et al.* (1986).

50. Red-necked Francolin

Francolinus afer

French: Francolin à gorge rouge **German:** Rotkehlfrankolin **Spanish:** Francolín Gorgirrojo
Other common names: Bare-throated Francolin, Red-necked Spurfowl; Cranch's Francolin (*cranchii*)

Taxonomy. *Tetrao afer* P. L. S. Müller, 1776, Benguela, Angola.

Forms superspecies with *F. leucoscepus*, *F. rufopictus* and *F. swainsonii*, although *F. swainsonii* sometimes excluded because of overlap with present species. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Several other races have been described, but doubtfully valid: *loangwae* included in *melanogaster*; and *intercedens* in *cranchii*; validity of several of the races currently accepted is also doubtful. Race *cranchii* (incorporating *leucoparaeus* and *harterti*) has been separated as distinct species. Nominate *afer* hybridizes with *F. swainsonii* near Harare, NE Zimbabwe. Seven subspecies currently recognized.

Subspecies and Distribution.

F. a. cranchii (Leach, 1818) - W Congo E to E Africa, around L Victoria, and S to NE Zambia.
F. a. harterti (Reichenow, 1909) - around N shore of L Tanganyika in Ruzizi Valley, Burundi, and NE Tanzania and E Zaire.

F. a. leucoparaeus Fischer & Reichenow, 1884 - Kenya, from R Tana to Tanzanian border.

F. a. afer (P. L. S. Müller, 1776) - W Angola and extreme NW Namibia.

F. a. melanogaster (Neumann, 1898) - Mozambique (N of R Zambezi), E Tanzania and E Zambia.

F. a. swynnertoni (W. L. Sclater, 1921) - SE Zimbabwe E to C Mozambique (S of R Zambezi).

F. a. castaneiventris (Gunning & Roberts, 1911) - South Africa, from S & E Cape Province E to R Limpopo.

Introduced to Ascension I (S Atlantic).

Descriptive notes. c. 35 cm; male 480-907 g, female 370-652 g. Distinctive scarlet throat and red bill and legs, separate present species from *F. swainsonii* and *F. rufopictus*. Female averages smaller, with much shorter spurs. Immature appears duller and browner, with bill dark horn. Races separated by size, head pattern and underpart colouring: black and white (*afer*, *swynnertoni*, *melanogaster*, *leucoparaeus*), and vermiculated/rufous-striped (*castaneiventris*, *cranchii*, *harterti*) subspecies groups recognized; groups intergrade on two fronts, one from C Tanzania S through Malawi to E Zambia, and the other from NW Zimbabwe through to N & C Angola. Black and white group more variable and typified by heavily marked black and white underparts, and wing length usually over 18 cm, except in nominate *afer*; vermiculated/rufous-striped group characterized by vermiculated underparts, and wing length usually less than 18 cm.

Habitat. Wide range of brushy habitats, varying according to locality: in South Africa, wooded gorges and evergreen forest fringes; in Zambia, especially in damp grass and *Brachystegia* and mopane woodland; in Zimbabwe, thickets and moist vegetation; in Zaire and Uganda, grassland littered with thickets; in Tanzania, grassland with trees and bushes; on Kenyan coast, forest interspersed with grassland. Where sympatric with other francolins, especially *F. swainsonii* and *F. leucoscepus*, occurs in denser, more moist vegetation, mainly along watercourses.

Food and Feeding. Diet varies with season and locality: in Zaire, mainly small tubers; in S Africa, mostly vegetable matter (tubers, roots and bulbs, shoots, berries and fruit, and fallen crops) and some insects and their larvae, including termites on the wing; in Zimbabwe, invertebrates, grass shoots and seeds during warm and wet months, switching to seeds and underground bulbs and roots in cool, dry months. Will take ticks off grass stalks.

Breeding. Mostly lays late in rains, with chicks emerging amongst dense cover of early dry season: lays cool dry season, Apr-Aug, in E South Africa; wet and dry seasons, Jan-Jul (mainly Apr) and Nov-Dec (mainly Dec), in Zimbabwe; Mar-Jun in Angola; Nov-Jul in Zambia; Jan-Aug in Malawi; most months, but depending on locality, in E Africa. Monogamous and territorial. Male defends area around nest, chasing off other males. Nest is a hollow on ground made by female, often partly lined with grass, feathers or similar material, in long grass at base of tree or bush. Usually 3-9 eggs; incubation in captivity 23 days, eggs hatching synchronously; downy chicks have broad blackish central stripe above, yellow-buff below with some black; pin feathers emerge within 2 days, wing feathers at 4 days, flight at 10 days, sibling aggression at 39 days; chicks nearly fully-grown at 3-4 months. May breed at one year old, when family groups dissolve.

Movements. Sedentary. Flies only short distances of 50-100 m, and only when pressed, preferring to run into cover.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout c. 5,000,000 km². Generally common to abundant, with densities of 34-44 birds/km² reported from sites in Queen Elizabeth and Lake Mburo National Park, Uganda; possibly over 1,000,000 birds in South Africa; known to have declined near Harare, NE Zimbabwe, and in Zaire.

Shooting season should be restricted to Aug-Nov in Zimbabwe, where species confined to Mashonaland Plateau in Eastern Districts. Otherwise not in need of conservation attention.

Bibliography. Abe (1993), Baker (1981), Bannerman (1953), Benson (1963), Benson & Benson (1975), Britton (1980), Chapin (1932), Clancey (1967), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Ginn *et al.* (1989), Hall (1963), Hartley & Mundy (1992), Irwin (1971), Jackson & Sclater (1938), Komen (1991b), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957-1973), Maclean (1993), Peek (1972), Pinto (1983), Pomeroy & Abe (1992), Roles (1973), Snow (1978), Urban *et al.* (1986), Verschuren & Mankarika (1982), Vincent (1934).

51. Swainson's Francolin

Francolinus swainsonii

French: Francolin de Swainson **German:** Swainsonfrankolin **Spanish:** Francolín de Swainson
Other common names: Swainson's Spurfowl

Taxonomy. *Perdix Swainsonii* A. Smith, 1836, Kurrichane, western Transvaal.

Forms superspecies with *F. leucoscepus*, *F. rufopictus* and *F. afer*, although present species sometimes excluded because of overlap with *F. afer*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Several other races have been described, but doubtfully valid: *damarensis*, *gilli* and *chobiensis* all included in nominate *swainsonii*. Hybridizes with *F. afer* near Harare, NE Zimbabwe, and with *F. natalensis* in Bulawayo, SW Zimbabwe. Two subspecies recognized.

Subspecies and Distribution.

F. s. lundazi C. M. N. White, 1947 - N & W Zimbabwe and S Mozambique.

F. s. swainsonii (A. Smith, 1836) - SE Angola, N Namibia and N Zambia S to NE South Africa (N Natal, Transvaal).

Descriptive notes. Male c. 38 cm, female c. 33 cm; male 400-875 g, female 340-750 g. Black upper mandible and legs prevent confusion with *F. afer* and other bare-throated francolins. Female smaller, darker and more heavily patterned than male; spurs much reduced. Immature paler and duller. Races are considered rather poorly defined: populations in N Namibia, Botswana and W Zimbabwe vary locally and have characters resembling both of accepted races; those of Namibia and Botswana more closely resemble *swainsonii*, while those of Zimbabwe seem closer to *lundazi*; race *lundazi* smaller and paler.

Habitat. Savanna and bush, not far from water: prefers dense grassland near grain fields and water, but also found in country with good cover; sometimes at forest edge or in forest, and especially in grass along watercourses. In South Africa, occurs especially in dense grassland close to water and farmland; in Zimbabwe, favours thickets at forest edge and along streams. More dependant on water than most other African francolins.

Food and Feeding. Bulbs, tubers and roots, seeds, berries and grass leaves, together with some spiders and insects, including locusts, ticks, beetles and grasshoppers, and small molluscs. Grain crops also taken, especially fresh maize sprouts. In Transvaal: 30% maize, wheat and beans and other crops; 25% seeds of native plants, mainly pioneer grasses such as *Urochloa*, *Eleusine*, *Panicum* and *Digitaria*, as well as *Juncus* and *Concorus*; 14% roots and corns, predominantly *Cyperus*; 7% arthropods; and 2% green leaves. In summer arthropods constitute up to 20% of crop weight; in winter and spring feeds mostly on cultivated crops. Feeds and drinks in early morning and late afternoon.

Breeding. Lays in all months depending on locality: in South Africa Dec-May, sometimes any month, or even twice in one year; during at least part of period Feb-May in Swaziland, Botswana and Namibia; Nov-Aug (mainly Feb-Mar) in Zimbabwe; recorded at various times of year in Mozambique; May-Jul and Dec in Zambia. Monogamous and territorial. Nest is a hollow on ground lined with grass, leaves and similar material, concealed amongst cover. Usually 4-8 eggs; incubation c. 21 days; downy chicks have dark, rich brown broad central stripe above, and buffy underparts. Survival rate believed to be high, with mean of c. 6 chicks in broods in Transvaal.

Movements. Sedentary. Prefers to escape predators by running, but is a fast flier and can avoid raptors when on the wing.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout c. 1,500,000 km². Generally common to abundant over much of range. Possibly over 1,000,000 birds in South Africa where numbers are stable and range increasing; occurs in several protected areas, but likely to survive outside such areas without special protection. Moves into cultivation and has even displaced *F. afer* in farmland around Harare, NE Zimbabwe. During 1972 season, c. 6700 individuals were shot in Zimbabwe; recommendation that shooting should now be restricted to period Aug-Nov. Otherwise not in need of conservation attention.

52. Jackson's Francolin

Francolinus jacksoni

French: Francolin de Jackson German: Jacksonfrankolin Spanish: Francolín de Jackson

Taxonomy. *Francolinus jacksoni* Ogilvie-Grant, 1891, Kikuyu, Kenya.

Forms superspecies with *F. erckelii*, *F. ochropectus*, *F. castaneicollis* and *F. nobilis*. Has been separated in genus *Oreocolinus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Birds of Mt Kenya have been ascribed to race *pollenorum* and those of the Cherangani Hills to race *patriciae*, but neither of these races is generally accepted. Monotypic.

Distribution. Mountains of WC Kenya.

Descriptive notes. c. 38 cm; two males 1064 g and 1130 g. Differs from *F. castaneicollis* in more regularly patterned underparts and little or no blackish colouring on forehead and face. Female averages smaller than male, with much reduced spurs. Immature duller above and barred. Individuals of Mt Kenya are somewhat darker than birds in W.

Habitat. Montane forest and various habitats in alpine zone from 2200 m to 3700 m, including juniper and bamboo forest and moorland thickets; typically found in *Juniperus*, *Podocarpus*, *Hagenia* and *Hypericum* forest, *Arundinaria alpina* bamboo, and moorland

Erica and *Stoebe* thickets. Not usually within forest, but typically in thick shrub cover, and especially abundant in heath, e.g. plentiful in giant heath in Aberdare Range, and where scrub has replaced dead bamboo. Does venture into open patches, such as those of short Kikuyu grass, and also onto roadside verges in some places.

Food and Feeding. Bulbous roots and grass shoots, berries when available and small snails and insects; seeds in patches of dying bamboo. In dry weather emerges to feed before sunrise, and will feed throughout day.

Breeding. Lays Dec-Jan in Aberdare Range and on Mt Kenya; Jan-Feb, Aug, Oct and Dec in Mau Highlands; in high, wet ranges, may breed only during dry season. Monogamous and territorial. One nest found by bamboo clump, but structure undescribed. At least 3 eggs; up to 7 chicks seen in a brood, which stays with adult for about c. 8 months.

Movements. Sedentary. Moves out into open areas to dry plumage and dust-bathe during suitable weather.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout c. 50,000-60,000 km². Considered a candidate for inclusion in Red Data Book in 1985. Restricted range; occurs in Kenyan Mountains Endemic Bird Area. Locally common to abundant, at high densities in national parks; c. 900 km² of Mt Elgon Forest Reserve is at appropriate altitude. Species approaches humans quite closely in Aberdare National Park. Lower fringes of forest are disturbed, but species not in need of conservation attention at present. More detailed information on distribution and abundance required.

Bibliography. Betts (1966), Britton (1980), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1963), Hall & Moreau (1962), Jackson & Slater (1938), Komen (1991b), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957), Ripley & Bond (1971), Sessions (1967), Snow (1978), Turner (1977), Urban *et al.* (1986).

53. Handsome Francolin

Francolinus nobilis

French: Francolin noble German: Edelfrankolin Spanish: Francolín Noble

Taxonomy. *Francolinus nobilis* Reichenow, 1908, Virunga Volcanoes, Zaire.

Forms superspecies with *F. jacksoni*, *F. erckelii*, *F. ochropectus* and *F. castaneicollis*. Has been separated in genus *Oreocolinus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Birds of Ruwenzori Mts have been ascribed to race *chapini*, but this race not generally accepted. Monotypic.

Distribution. SW Uganda, Rwanda and Burundi to mountains of E Zaire.

Descriptive notes. c. 34 cm; two males 862 and 895 g, female 600-670 g. Distinctive combination of red bare parts, including patch of bare skin around eye, and dark rufous on most of underparts. Female smaller than male and somewhat duller, with much reduced spurs. Immature differs in having barred upperparts and rather paler underparts. Individuals from Ruwenzori Mts have belly feathers with narrower grey edges, a character which varies within populations elsewhere.

Habitat. Occurs from lower edge of montane forest, through areas of bamboo to alpine heath at c. 3700 m.

Food and Feeding. Feeds on seeds. Forages along roads in very early morning and late afternoon. Breeding. Laying from late Apr to Sept in S Kivu Province, E Zaire. Small groups have been seen, which were assumed to be family parties. No further information available.

Movements. Sedentary. Flies short distances and only when hard pressed, preferring to escape by running into cover.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout c. 130,000 km². A candidate for inclusion in Red Data Book in 1985. Considered to be generally common to locally abundant. In Uganda probably restricted to three national parks, but two of these contain areas of only 45 km² and 80 km² at suitable altitude; protected areas generally effective and maintenance of these is necessary for long-term survival. Not in need of

immediate conservation attention, but much more detailed information required on distribution and relative abundance.

Bibliography. Britton (1980), Chapin (1932), Crowe (1993), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Grant & Mackworth-Præd (1935), Hall (1963), Komen (1991b), Lappens & Wille (1976), Mackworth-Præd & Grant (1957, 1970), Pitman (1948), Prigogine (1971), Urban *et al.* (1986).

54. Mount Cameroon Francolin

Francolinus camerunensis

French: Francolin du Cameroun German: Kamerunfrankolin Spanish: Francolín del Camerún
Other common names: Cameroon Mountain/Cameroon Francolin

Taxonomy. *Francolinus camerunensis* Alexander, 1909 Mount Cameroon.

Forms superspecies with *F. swierstrai*. Has been separated in genus *Oreocolinus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Monotypic.

Distribution. Slopes of Mt Cameroon (W Cameroon).

Descriptive notes. c. 33 cm; male c. 593 g, female c. 509 g. Distinguished from rather similar *F. nobilis* by more extensive dark brown above and lack of chestnut or pale grey patterning on underparts. Female has distinctive appearance, with peculiar combination of red bare parts, barred upperparts and streaked and vermiculated underparts. Immature resembles adult female but is barred below, and has bill and legs dull red.

Habitat. Found in both primary and secondary forest where there is dense undergrowth. Occurs between 850 m and 2100 m in montane forest; seems to avoid montane grassland

on upper slopes of Mt Cameroon.

Food and Feeding. Berries, grass seeds and insects.

Breeding. Breeds during the dry season, with birds laying between Oct and Dec. No further information available.

Movements. Sedentary. Will fly to trees to escape dogs, but otherwise runs when alarmed.

Status and Conservation. RARE Mace-Lande: Vulnerable. Restricted to 200 km² on SE & NE slopes of Mt Cameroon. Originally collected from above Musaka and then from above Buea, both on SE slopes of mountain; heard from SW slopes above Isongo in 1938; birds seen and heard on a few occasions above Buea since 1970, especially during survey work in early 1980's, and also on NE slopes at the same time. Said to be locally common, especially on S slopes of mountain, where appears to be common down to 850 m. No evidence of marked population decline: much of forest on Mt Cameroon has suffered damage, but species appears to be able to tolerate secondary forest; access to mountain is controlled to some extent in places. Restricted range; occurs in Cameroon Mountains Endemic Bird Area. In 1982 a large area of suitable habitat in this very small range was destroyed by a volcanic eruption. Species may also be overhunted. Surveys should attempt to determine requirements and assess feasibility of habitat protection.

Bibliography. Alexander (1909), Bannerman (1915, 1930, 1953), Boulton & Rand (1952), Collar & Andrew (1988), Collar & Stuart (1985), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Eisenstat (1956, 1963), Grimes (1971), Hall (1963), Jensen & Stuart (1985), Komen (1991b), Louette (1981), Mackworth-Præd & Grant (1970), Serle (1962, 1965, 1981), Stuart & Jensen (1986), Urban *et al.* (1986)

55. Swierstra's Francolin

Francolinus swierstrai

French: Francolin de Swierstra German: Swierstrafrankolin Spanish: Francolín de Swierstra

Taxonomy. *Chaetopus swierstrai* Roberts, 1929, Mombolo, south-west Cuanza Sul, Angola.

Forms superspecies with *F. camerunensis*. Has been separated in genus *Oreocolinus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. *F. cruzi* is a synonym. Monotypic.

Distribution. W Angola, from Cuanza Sul District to Huila District.

Descriptive notes. c. 33 cm; male c. 600 g, female c. 560 g. Diagnostic broad black band on breast. Female has some buff streaking on upperparts, and much reduced spurs. Immature resembles female with barred belly and more buff above.

Habitat. Montane evergreen forest and forest edge, boulder strewn mountain sides, and tall grass on mountain tops and in gullies. In forest stays within dense undergrowth of bushes, shrubs, grasses and large ferns. Dependence on forest not clear.

Food and Feeding. Grasses, legume seeds and insects, picked from amongst leaf litter.

Breeding. Virtually unknown; believed to breed May-Jul, based on gonadal development of specimens.

Movements. Sedentary.

Status and Conservation. INDETERMINATE Mace-Lande: Vulnerable. CITES II. Has restricted range and is apparently rare within it. A few remnant forest blocks still persist on e.g. Mt Moco and Mt Soque. Probably declining in view of habitat destruction that is in progress. If dependent on forest to a large degree, species is likely to be seriously threatened by loss of this habitat, much of which has already disappeared: a few km² in the Bailundu Highlands and on the scarp may have been all that remained in 1962; since then, a population was found to N. at E. Angango, but extent of habitat available to species probably very small. Occurs in Angola Endemic

On following pages: 56. Chestnut-naped Francolin (*Francolinus castaneicollis*); 57. Erckel's Francolin (*Francolinus erckelii*); 58. Umbou Francolin (*Francolinus ochropectus*); 59. Grey Partridge (*Perdix perdix*); 60. Daorian Partridge (*Perdix dauirica*); 61. Tibetan Partridge (*Perdix hodgsoniae*); 62. Long-billed Partridge (*Rhizothera longirostris*); 63. Madagascar Partridge (*Margaroperdix madagarensis*); 64. Black Wood-partridge (*Melanoperdix nigra*).

Bird Area. Some conservation work is under way, but details are lacking. An extensive survey is needed to identify status, threats and propose actions for habitat protection.

Bibliography. Collar & Andrew (1988), Collar & Stuart (1985, 1988a), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1960a, 1963), Hall & Moreau (1962), Heinrich (1958), King (1978/79), Komen (1991b), Pinto (1970, 1983), Roberts (1929), Themido (1937), Traylor (1960a, 1960b, 1963), Urban *et al.* (1986), White (1945).

56. Chestnut-naped Francolin

Francolinus castaneicollis

French: Francolin à cou roux

Spanish: Francolín Cuellicastaño

German: Braunnackenfrankolin

Other common names: Ethiopian Francolin (*atrifrons*)

Taxonomy. *Francolinus castaneicollis* Salvadori, 1888, Lake Ciar-Ciar (= Chercher), Hararghe, Ethiopia.

Forms superspecies with *F. jacksoni*, *F. nobilis*, *F. erckelii* and *F. ochropectus*. Has been separated in genus *Oreocolinus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Several other races have been described, but validity doubtful; *bottegi*, *ogonensis*, *kaffanus*, and *gofanus* all included in nominate *castaneicollis*. Race *atrifrons* has been considered to be specifically distinct. Two subspecies recognized.

Subspecies and Distribution.

F. c. castaneicollis Salvadori, 1888 - Ethiopia and Somalia.

F. c. atrifrons Conover, 1930 - S Ethiopia and extreme N Kenya.

Descriptive notes. c. 33-5 cm; male 915-1200 g, female 550-650 g. Black forehead and creamy white belly separate from otherwise rather similar *F. jacksoni*; from *F. erckelii* and *F. ochropectus* differs by red bill and legs, and by underpart pattern. Female averages smaller than male, with much reduced spurs. Immature duller. Variation is clinal, with birds from Somalia paler than those from NE Ethiopia, while those from Jimma and Kaffa Provinces are richer chestnut; race *atrifrons* lacks chestnut on breast and upperparts and distinct markings on belly of *castaneicollis*.

Habitat. Forest, glades and undergrowth, altitude limits appearing to vary with locality. Recorded between 1200 m and 2250 m in arid juniper forest in Bale and Arussi Mts of Ethiopia; along edges of broad-leaved forest in Kaffa and Jima Provinces. Optimum habitat considered to be *Hagenia/Hypericum* forest with wet, dense undergrowth of red-hot poker lilies (*Knifophia*) and giant *LOBELIA*, at 3100-3500 m.

Food and Feeding. Seeds and insects such as termites. Forages in coveys, picking food from ground, or taking it from plant heads, rather than by digging. Rarely forages in fields, but may take fallen grain in some areas. Will feed throughout day, especially in morning and evening.

Breeding. Lays Oct-Mar in Ethiopia; May (wet season) and Dec (dry season) in Somalia. Probably monogamous. Nest is a depression under cover. Usually 5-6 eggs. Young stay with parents until fully-grown; family parties of 5-8 suggest that breeding success may be high.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout range of c. 270,000 km². Generally common to abundant, but superabundant in Bale and Arussi Mts in Ethiopia; more common to E of Rift Valley than to W; less common in Somalia. Probably stable in Ethiopia; trend in Somalia not known, but widespread habitat degradation continues. Not in need of conservation attention.

Bibliography. Ash (1992), Ash & McKell (1983), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1963), Komen (1991b), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957), Raethel (1988), Urban *et al.* (1986).

57. Erckel's Francolin

Francolinus erckelii

French: Francolin d'Erckel

German: Erckelfrankolin

Spanish: Francolín de Erckel

Taxonomy. *Perdix erckelii* Rüppell, 1835, Taranta Mountains, Ethiopia.

Forms superspecies with *F. jacksoni*, *F. nobilis*, *F. castaneicollis* and *F. ochropectus*. Has been separated in genus *Oreocolinus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Proposed race *pentoni* not considered valid. Monotypic.

Distribution. N Ethiopia, including Eritrea; also Red Sea Province, Sudan.

Introduced to Hawaii.

Descriptive notes. 39-43 cm; 1050-1590 g. Very large size; upperparts more olive brown overall than in similar *F. ochropectus*; black bill and yellowish legs prevent confusion with *F. castaneicollis*. Female smaller, with much reduced spurs. Immature barred and streaked on paler grey upperparts. Isolated population in Sudan is paler.

Habitat. Blocks of scrub, consisting of *Carissa*, *Rumex*, *Maytenus* and *Rosa abyssinica*; forest remnants with tall *Hyparrhenia* grass on hills between 2000 m and 3500 m; also *Erica arborea* heath in higher mountains and woods, along stream beds; much lower in

Sudan than in Ethiopia. Tends to remain at forest edge when tall forest available.

Food and Feeding. Seeds, shoots and berries, and some insects. Forages in scrub, at forest edge and in cultivation; feeds on sheer cliffs by flying from ledge to ledge.

Breeding. Lays in May and Sept-Nov, during rains; in Ethiopia; and Apr-May, during rains, in N Sudan. Probably monogamous. Nest is a scrape on the ground. Usually 4-10 eggs; chicks have dark brown and black down above, brownish white below. Both parents stay with young; young birds known to suffer predation by baboons.

Movements. Sedentary. Runs uphill when alarmed; if pursued, flies back downhill.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Occurs in suitable habitat throughout c. 220,000 km². Considered common and now probably stable in Ethiopia, although may be less widespread than in past, as many of forests in N have been destroyed. No information available regarding status of isolated population of Sudan. Not in need of conservation attention, but more detailed information required on distribution and relative abundance.

Bibliography. Ash (1992), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Hall (1963), Komen (1991b), Lever (1987), Mackworth-Præd & Grant (1957), Moltoni & Ruscone (1940-1944), Nikolaus (1987), Raethel (1988), Urban *et al.* (1986).

58. Djibouti Francolin

Francolinus ochropectus

French: Francolin somali

German: Wacholderfrankolin

Spanish: Francolín Somali

Other common names: Ochre-breasted/Tadjoura/Pale-bellied Francolin

Taxonomy. *Francolinus ochropectus* Dorst and Jouanin, 1952, Plateau du Day, Tadjoura, Djibouti. Forms superspecies with *F. jacksoni*, *F. nobilis*, *F. castaneicollis* and *F. erckelii*. Has been separated in genus *Oreocolinus*. Recently proposed reorganization of *Francolinus* places present species in genus *Pternistis* with 23 other species. Considered a weakly differentiated species, intermediate geographically and morphologically between *F. erckelii* and *F. castaneicollis*. Monotypic.

Distribution. Forêt du Day in Goda Mts and Maba Mts of Djibouti.

Descriptive notes. c. 33 cm; c. 940 g. Smaller and darker above than *F. erckelii*; black bill and yellow legs separate from *F. castaneicollis*. Female smaller than male, with more rufous in tail, and spurs much reduced. Immature resembles female, but is barred buff and grey.

Habitat. Occurs in c. 1500 ha of primary juniper forest above 700 m; main plant species are *Juniperus procera*, which may grow to 8 m tall, and *Buxus hildebrandtii* and *Clusia abyssinica* which make up the understorey. Elsewhere associated with *Ficus*, *Acacia seyal* and *A. etbaica*. Also found in secondary forest

and may occur in degraded habitat.

Food and Feeding. Seeds, berries and termites. Also feeds on figs at forest edge, where a parasitic *Ficus* occurs. When searching for food, rakes over ground, including areas disturbed by warthogs.

Breeding. Laying in Dec-Feb; family of 9 individuals seen in Mar, a period when genets (*Genetta genetta*) are major predators. No further information available.

Movements. Sedentary.

Status and Conservation. ENDANGERED. Mace-Lande: Endangered. Very limited range, with 3500 ha of habitat known at 2 sites; there is a slight possibility of species occurring elsewhere; available habitat was halved between 1977 and 1983. Main site is Forêt du Day, which is now c. 1400-1500 ha in extent, within area of c. 100 km² which have been designated a national park. Range is in zone affected by war at present. Probably fewer than 1000 birds survive, although there were possibly 5000 in 1986, so a decline is inferred. Threatened by habitat degradation through grazing and firewood collection; also by overexploitation, with eggs and some birds taken for food, although extent unknown. Designation of Maba Mts as a protected area is desirable, in conjunction with appropriate management and environmental education; protection of existing Forêt du Day National Park should be improved. As numbers are so low, and believed to be concentrated in two sites, an extensive survey of all known and possible localities within range should be conducted, to try to assess exact numbers; research into ecological requirements is also necessary, in order to guide management strategies; a Population and Habitat Viability Assessment is needed, to clarify conservation management options.

Bibliography. Ash (1992), Blot (1985), Collar & Andrew (1988), Collar & Stuart (1985), Crowe & Crowe (1985), Crowe & Kemp (1986), Crowe *et al.* (1992), Dorst & Jouanin (1952, 1954), Hall (1963), Hall & Moreau (1962), King (1978/79), Komen (1991b), Laurent (1990), Urban *et al.* (1986), Welch & Welch (1984, 1985, 1986), Welch *et al.* (1986).

Genus PERDIX: Brisson, 1760

59. Grey Partridge

Perdix perdix

French: Perdrix grise

German: Rebhuhn

Spanish: Perdiz Pardilla

Other common names: Common Partridge

Taxonomy. *Tetrao Perdix* Linnaeus 1758, Europe = Sweden.

Internal taxonomy needs revision. Proposed race *italica* normally included within nominate *perdix*. Seven subspecies currently recognized.

Subspecies and Distribution.

P. p. hispaniensis Reichenow, 1892 - NE Portugal and N Spain.

P. p. amurica Hartert, 1917 - Normandy and C France N to Ardennes and Morvan Mts.

P. p. sphagnetorum (Altum, 1894) - NE Netherlands and NW Germany.

P. p. perdix (Linnaeus, 1758) - British Is and Scandinavia to Alps and Balkans.

P. p. lucida (Altum, 1894) - Finland E to Ural Mts and S to Black Sea and N Caucasus.

P. p. canescens Buterlin, 1906 - Turkey, Caucasus, Transcaucasia and Iran.

P. p. robusta Homeyer & Tancré, 1883 - basin of lower R Ural E through Kazakhstan to SW Siberia and NW China (Xinjiang).

Introduced and reintroduced to many parts of Europe, including Finland, Britain, Russia and France; also successfully introduced to USA and Canada.

Descriptive notes. 29-31 cm; 310-455 g; wingspan 45-48 cm. Very variable, especially in terms of greyer or browner plumage. Distinguished from very similar *P. daurica* by darker, browner plumage and grey breast without extensive orange cinnamon tinge. Chestnut patch on breast may be absent in female; female slightly darker in summer. Immature has broader bars on wing and

browner legs. Considerable individual variation within each race, but races in W usually more rufous brown, those in E generally paler and greyer.

Habitat. Grassland in temperate zone, steppe regions and open arable landscapes. Typically found in large tracts of grassland, or in other ground cover that is only slightly taller than the bird itself, with some dense shrubby patches, e.g. hedgerows, at intervals. Seeks proximity of ploughed fields, dunes and other kinds of open area. Much of species' original habitat is now under agriculture, but it appears to be reasonably adaptable to some less in-

tensive practices.

Food and Feeding. Feeds on seeds of grains and weeds, cereals and clover, and grass leaves; insects such as Coleoptera, aphids and bugs. Studies in many countries show that in autumn food consists mainly of green leaves of grasses (Gramineae), cereals and clover (e.g. *Trifolium*) and grain and weed seeds (especially *Polygonum*). In spring and summer, seed heads of chickweed (*Stellaria*) and unripe grass seeds are preferred in Britain. Proportion of weed seeds in autumn diet dropped from 31% (by dry weight) in 1933-1936 to 4% in 1968-1977; this drop attributed to use of herbicides and change in stubble removal practices. Chicks dependent on insects in first 2 weeks of life; proportion in diet varies between studies, but at least half volume of intake. Insects eaten include larvae of sawflies which eat cereal leaves, Hemiptera, Heteroptera and other larger bugs, various beetles, and cereal aphids.

Breeding. Laying from late Apr in Britain; early May to Jun in C Europe; and late May to June in Sweden; reneesting until Aug-Sept. Usually monogamous, but in some cases male with 2 females for up to 2 weeks; pairing up to 4 months before breeding, with changes of mate common during that period; pairs may reunite in following breeding season. Territorial, but boundaries not defended; copulation, nesting and some feeding all within territory; after chicks hatch, territories break up. Nest is a shallow depression lined with leaves and grass, at base of hedge or in other thick vegetation. First clutch 15-17 eggs (4-24); clutch smaller when reneesting; incubation 23-25 days, usually by female alone; downy chicks have rufous, chestnut and black markings on buff upperparts, creamy yellow underparts; capable of precocial flight after c. 2 weeks; adult weight at c. 100 days. Chick survival to 6 weeks very variable. Sexual maturity in first year.

Movements. Mainly sedentary, but in E Europe is partially migratory, and nomadic in bad weather. Performs altitudinal movements in Caucasus, descending to foothills in Oct-Nov. Flight is fast and strong, but usually for no more than 2 km. In British Is, little movement in winter; coveys disperse locally in early spring.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Considered safe because still widespread and estimated to number several million birds. However, numbers have declined markedly in all parts of its native range for which bag records exist; since early part of present century, may have declined in all c. 31 countries in which it is found. Reduction in numbers believed to be as high as 80%; causes probably include factors such as loss of nesting cover, predation, and pesticides that reduce insect abundance in spring; all are consequences of intensification of agricultural practices. Specific recommendations to address these problems include: provision of good quality nesting cover; reduction of nest predation by controlling impact of foxes, stoats and feral cats; improving insect abundance in spring so that chicks have sufficient prey items.

Bibliography. Aebischer (1991), Beani & Dessì-Fulgheri (1986), Beani, Cervo & Dessì-Fulgheri (1988), Beani, Cervo, Lodi *et al.* (1988, 1992), Birkan (1971), Birkan & Jacob (1988), Birkan & Serre (1988), Birkan *et al.* (1992), Blank & Ash (1956, 1960), Blank *et al.* (1967), Carroll (1993), Cheng Tso-hin (1987), Church *et al.* (1990), Cramp & Simmons (1980), Dementiev & Gladkov (1952), Dessì Fulgheri *et al.* (1986, 1990), Dowell (1988, 1990), Dudzinski (1992), Etchécopar & Hùe (1978), Flint *et al.* (1984), Gossow *et al.* (1992), Illner (1992), Jenkins (1961), Jonsson (1992), Kavanagh (1992), King (1978/79), Kuz'mina (1992), Lever (1987), Lupo *et al.* (1990), Marchant *et al.* (1990), Nikiforov (1992), Novoa (1992a, 1992b), Panek (1987), Patrikeev (1993), Pielowski (1988), Potapov & Flint (1989), Potts (1986), Pulliainen (1984), Rands & Hayward (1987), Rasmussen *et al.* (1989), Reitz (1989, 1992), Reitz *et al.* (1984), Simeonov *et al.* (1990).

60. Daurian Partridge

Perdix dauurica

French: Perdrix de Daourie

German: Bartbrebhuhn

Spanish: Perdiz Daurica

Taxonomy. *Tetrao perdix* var. *dauurica* Pallas, 1811, Transbaikalia.

Sometimes erroneously spelt *P. dauuricae*. Formerly known as *P. barbata*. Proposed race *przewalski* included within race *suschkini*. Two subspecies recognized.

Subspecies and Distribution.

P. d. dauurica (Pallas, 1811) - Kirghizia and W China (Xinjiang) E to Mongolia and E Russia, S to Tuva Mts.

P. d. suschkini Poliakov, 1915 - C & NE China (Qinghai E to Heilongjiang).

Introduced and established around Manila (N Philippines).

Descriptive notes. c. 30 cm; 200-340 g. "Beard" of stiff feathers on sides of chin distinctive in autumn and winter. Differs from very similar *P. perdix* by paler and greyer plumage, less reddish face, extensive cinnamon patch on breast, and larger (male) and blacker patch on belly. Female more barred and vermiculated than male, with belly patch reduced or absent. Immature more coarsely marked above. Races similar.

Habitat. Variety of open habitats from grassland and meadows to wooded steppes and plantations; up to 3000 m in steppe regions of former USSR.

Food and Feeding. Very little information available. Takes seeds of weeds, cereals and berries; also insects in summer.

Breeding. Nesting from late May in Jilin and Shanxi (NE & NC China); pairing begins by mid-Mar in Altai region, where laying begins in late Apr. Nest is situated in or next to cover and lined with grass, leaves, roots and soft feathers. 35 clutches contained 18-20 eggs (minimum 12); incubation c. 25 days, by female only.

Movements. No information available, but some seasonal movements suspected in response to weather conditions.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Considered safe from extinction largely because of extensive range. In NE China considered common in Jilin, Hebei and Heilongjiang; in Jilin, numbers believed to be decreasing due to overhunting; average of 4-2 individuals were encountered along 3 km line transect in 1982 and 2-7 birds in 1990; little information from other parts of China, but hunters report decline in bags in Shanxi (NC China). In Transbaikalia, population size believed to have varied considerably over period of only a few years. Whilst population trends are unclear, species appears to be hunted throughout much of its range; monitoring of numbers shot in several areas throughout range would help to clarify status.

61. Tibetan Partridge

Perdix hodgsoniae

French: Perdrix de Hodgson

German: Tibetbrebhuhn

Spanish: Perdiz Tibetana

Other common names: Hodgson's Partridge

Taxonomy. *Sacca Hodgsoniae* Hodgson, 1857, Tibet.

Has been separated in monospecific genus *Sacca*. Three subspecies recognized.

Subspecies and Distribution.

P. h. sifanica Przevalski, 1876 - WC China, from C Qinghai and Gansu S to E Tibet and C & S Sichuan.

P. h. caraganae R. & A. Meinertzhagen, 1926 - NW India (E Kashmir) E to E Tibet.

P. h. hodgsoniae (Hodgson, 1857) - W Nepal E to NE India (Assam) and E Tibet.

Descriptive notes. c. 28 cm; male 294-370 g. Very distinctive head and neck pattern. Female slightly smaller than male. Immature duller, with no chestnut.

Habitat. Usually dry hillsides with scattered juniper bushes, and near cover such as crops, grass or brush; in summer generally above 3600 m and below 4600 m, but occurs up to 5600 m.

Food and Feeding. Virtually no information available; probably eats a variety of seeds and insects.

Breeding. Season from May to Jul, or even Aug. Nest is a scrape (20-22 cm in diameter) sometimes no nest at all. Lays 8-10 eggs

in the ground, lined with grass, situated under cover; sometimes no nest at all. Lays 8-10 eggs (6-12). No further information available.

Movements. Very little information available; in India found between c. 3600 m and 5600 m; usually below 4000 m in winter, and sometimes down to 2800 m. Flies only if pressed, birds "exploding" downhill when flushed.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Believed safe, as widely distributed and considered fairly common in China and locally quite common in India. No other information on status or threats available. Whilst its two congeners are widely hunted, present species occurs at higher altitudes, in areas that seem to be largely free from human pressures.

Bibliography. Ali & Ripley (1980), Baker (1930), Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Etchécopar & Hùe (1978), He Fen-qi & Cui Xie-zhen (1990), Inskipp & Inskipp (1985), King & Peng Ji-tai (1991), Mallon (1987), Meyer de Schauensee (1984), Robson (1986).

Genus RHIZOTHERA G. R. Gray, 1841

62. Long-billed Partridge

Rhizothera longirostris

French: Perdrix à long bec

German: Langschnabelwachtel

Spanish: Perdiz Piquilarga

Other common names: Long-billed Wood-partridge

Taxonomy. *Perdix Longirostris* Temminck, 1815, Sumatra.

Two subspecies recognized.

Subspecies and Distribution.

R. l. longirostris (Temminck, 1815) - S Burma and S Thailand S through Malay Peninsula to Sumatra; W & S Borneo.

R. l. duliensis Ogilvie-Grant, 1895 - mountains of N Borneo.

Descriptive notes. c. 37 cm; male c. 800 g, female c. 697 g. Long, fairly stout decurved bill distinctive. Female all rich rufous below; can have spurs. Immature resembles female, but has some barring on flanks and breast. Race *duliensis* differs mainly in all whitish belly.

Habitat. Dry forest, especially in areas with bamboo, from sea-level up to 1000-1500 m, including high level tea estates in Sumatra. Favours limestone hills.

Food and Feeding. Berries, grasses, seeds and insects.

Breeding. Only one nest known, found in Feb

containing 2 eggs, a shallow scrape lined with root fibre and bamboo leaves, placed amongst bamboo bushes. In captivity: lays 2-5 eggs; incubation 18-19 days.

Movements. No information available; presumably sedentary.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. Never widely encountered, as calling is very sporadic, status and trend therefore implied from state of its known

habitat. Possibly extinct in Thailand from where there are no recent records; sparsely distributed in Malaysia (both Peninsular and Bornean); present in Gunung Leuser National Park in N Sumatra, and possibly also at Ulu Barito in Kalimantan. Most historical sites in Kalimantan now largely deforested; this is probably also true for Sumatra and Peninsular Malaysia. Whilst most known sites are in lowlands, species does occur in lower montane forest, in Indonesia at least, and such habitat is still widespread in Sumatra and Peninsular Malaysia. Not recorded in any protected area in Thailand, although may occur in one or two; known from Krau Wildlife Reserve (530 km²), Taman Negara National Park (4343 km²) and Fraser's Hill Wildlife Sanctuary (30 km²) in Peninsular Malaysia, and Danum Valley Research Centre in Sabah, NE Borneo; in Indonesia, recorded in Gunung Leuser National Park (7927 km²) in N Sumatra, but no records from any protected area in Kalimantan; not protected by Indonesian law. Threatened by loss and alteration of habitat which takes place in variety of ways; clear-felling of forest for timber, loss of forest to agriculture and habitat degradation. CITES III in Malaysia.

Bibliography. Andrew (1992), Baker (1935), van Balen (1992), Chasen (1939), Crowe & Crowe (1985), Davison & Scriven (1987), Gibson-Hill (1949), Holmes (1989), Johns (1986, 1989), Lekagul & Round (1991), MacKinnon & Phillips (1993), Mudoc (1976), van Marle & Voous (1988), Medway & Wells (1976), Robinson & Chasen (1936), Robinson & Kloss (1921, 1924), Round (1988), Schönwetter (1967), Showler (1993), Smythies (1957, 1981), Wells (1985).

Genus *MARGAROPERDIX*

Reichenbach, 1853

63. Madagascar Partridge

Margaroperdix madagarensis

French: Perdrix de Madagascar

German: Perlwachtel

Spanish: Perdiz Malgache

Taxonomy. *Tetrao madagarensis* Scopoli, 1786, Madagascar.

Emendation of species name to *madagascarensis* is not justified. Monotypic.

Distribution. Madagascar.

Introduced to Reunion.

Descriptive notes. c. 26-30 cm; c. 220 g. Small hindclaw. Male quite unmistakable, with striking patterns on head and underparts. Female all dull brownish, but distinctively patterned below with large scallops. Immature undescribed, but apparently similar to female.

Habitat. Forest areas and brushland, mostly frequenting secondary habitats; also found in grassland and weedy farmland. Occurs from sea-level to 2700 m.

Food and Feeding. No information available; probably feeds on seeds, berries, roots and insects.

Breeding. Nests in Mar-Jun. Nest situated on the ground, well hidden in a tuft of grass. Lays 15-20 eggs; downy young similar to those of *Coturnix*.

Movements. No information available; presumably sedentary.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. Formerly common in the E & C regions of island; anecdotal evidence indicates serious decline since 1930's; could now be very scarce, and numbers might have decreased more than is currently thought. Considered a candidate for inclusion in Red Data Book in 1985. A population estimate in the tens of thousands is based only on extent of distribution and comments on relative abundance. Occurs in several protected areas, comprising 2 national parks, 6 integral reserves and 5 special reserves. Potentially

4266 km² of protected area in 13 blocks which may be suitable for species. Also recorded in 8 out of 18 Sites of Biological Interest which are proposed as additions to protected area network. Threatened by habitat degradation resulting from annual fires which are converting brushland to grassland; also heavily exploited through hunting with dogs, and is caught by trappers using rice-baited snares.

Bibliography. Crowe & Crowe (1985), Dee (1986), Frost (1975), Langrand (1990), Milon *et al.* (1973), Nicoll & Langrand (1989), Raethel (1988), Rand (1936), Schönwetter (1967).

Genus *MELANOPERDIX* Jerdon, 1864

64. Black Wood-partridge

Melanoperdix nigra

French: Perdrix noire

German: Schwarzwachtel

Spanish: Perdiz Negra

Other common names: Black Partridge

Taxonomy. *Cryptonyx niger* Vigors, 1829, no locality.

Two subspecies recognized.

Subspecies and Distribution.

M. n. nigra (Vigors, 1829) - Peninsular Malaysia and Sumatra.

M. n. borneensis Rothschild, 1917 - Borneo.

Descriptive notes. c. 24-27 cm; c. 260 g. Male very distinctive, showing combination of short thick bill and glossy black plumage. Peculiar bill distinguishes female from other predominantly chestnut species: upperparts almost unmarked. Immature male resembles female; immature female is paler above, with blackish vermiculations. Races similar.

Habitat. Primary lowland forest, usually with many spiny stemless palms in undergrowth; also in wetland forest in Sumatra and Kalimantan. Down to sea-level, but upper altitude limit unknown; has been reported recently at 1200 m in Ulu Barito, Kalimantan.

Food and Feeding. No information available.

Breeding. Little information available. One clutch of 2 eggs found in Jan, one of 3 in May, and three of 5 eggs in Sept, all in Borneo; downy young seen in late Oct. Incubation 18-19 days (in captivity).

Movements. No information available; presumably sedentary. Runs when disturbed, although typically sits tight until approaching human is only a few metres away.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. Currently considered near-threatened. Believed to be very sparsely distributed in Peninsular Malaysia and probably also in Indonesia. Extreme scarcity of records makes any population estimate very difficult, but numbers presumed to be decreasing; never widely encountered, and status and trend therefore implied from current state of known habitat. Wetland and peat swamp forest still widespread in Indonesia but even this habitat type is now becoming threatened. Occurs in Pasoh Forest Reserve, Krau Wildlife Reserve and Gunung Mulu National Park in Malaysia; and, in Indonesia, in Berbak Game Reserve in Sumatra, and Tanjung Puting National Park and Gunung Palung Nature Reserve in Kalimantan. Not protected by Indonesian law. Threatened by habitat loss and alteration: clear-felling for timber; forest loss to agriculture; and forest degradation. Clarification of species' distribution, especially in protected areas, is required, as is general research. CITES III in Malaysia.

Bibliography. van Balen (1992), Chasen (1939), Coomans de Ruiter (1946), Crowe & Crowe (1985), Davison & Scriven (1987), Dutson (1990), Gibson-Hill (1949), Holmes (1989), MacKinnon & Phillips (1993), van Marle & Voous (1988), Medway & Wells (1976), Riley (1938), Robinson & Chasen (1936), Schönwetter (1967), Smythies (1957, 1981), Wells (1985).

Genus *COTURNIX* Bonnatere, 1791

65. Japanese Quail

Coturnix japonica

French: Caille du Japon **German:** Japanwachtel **Spanish:** Codorniz Japonesa
Other common names: Asian Migratory Quail

Taxonomy. *C. vulgaris japonica* Temminck and Schlegel, 1849, Japan. Forms superspecies with *C. coturnix*, and possibly also with *C. pectoralis*. Present species has been considered a race of *C. coturnix*, but they are apparently sympatric in Mongolia. Monotypic. **Distribution.** Breeds in E Asia, from N Mongolia, NE through Baikal region to Vitim region in EC Russia, E to Sakhalin I, and S to Japan, Korea and NE China (E Shandong); winters S from C Japan and C China W through NW Thailand and N Burma to NE India (Assam) and Bhutan. Records from NW Bangladesh usually ascribed to *C. coturnix*, but may actually be applicable to present species. May breed in Buthan and Burma. Introduced to Hawaiian Is.

Descriptive notes. c. 17-19 cm; c. 90 g. Usually indistinguishable in the wild from *C. coturnix*, except on call; in the hand, distinguished by having wing under 10.5 cm long, small "beard" in autumn and winter, and more rufous coloration in spring. Some males may show partial collar on throat. Female differs from that of *C. coturnix* in pattern of underparts; intermediate forms known to occur. Immature male has throat like female, but suffused with brick red in centre.

Habitat. Little information available; open habitats in similar situations to those used by *C. coturnix*, but possibly damper meadows.

and also steppes and dry mountain slopes near water. Records from Bangladesh in grassland and cultivation.

Food and Feeding. Wide variety of plant materials; in summer, also takes terrestrial invertebrates. **Breeding.** Laying (including renests) from late Apr to early Aug in Russia; late May to Aug (Sept) in Japan; Mar-Jul (possibly present species) in NW Bangladesh. Usually 9-10 eggs in Russia, 5-8 in Japan; incubation 18 days, by female only.

Movements. Annual migrations; in Japan, of over 1000 ringed birds recovered, only 3 originated outside Japanese islands; a few birds winter in Russia, apparently coming from more northerly parts; breeds in N & NE China and winters in S China, including Hainan and Taiwan.

Status and Conservation. Not globally threatened. Mace-Landé: Safe. No reliable estimates of numbers, but species considered fairly common in China. Formerly regarded as widespread on Taiwan, where was fairly plentiful in E Kurenko District, but few recent records. Suitable habitat probably widespread in NW Thailand, but too few records to estimate abundance; sometimes considered only rare migrant to the country. Very few records from Bhutan as well, where was common in 1930's; also visits Assam, NE India, in small numbers. Clearly species is poorly known, and lack of records is a cause for concern. Loss and degradation of habitat are problems in some areas, e.g. Taiwan, but actual or potential threats are not known for most of range.

Bibliography. Ali & Ripley (1980), Austin (1948), Birkhead & Fletcher (1994), Brazil (1992), Cheng Tso-hin (1987), Clements (1992), Deignan (1945), Dementiev & Gladkov (1952), Dickinson *et al.* (1991), Etchécopar & Hue (1978), Fenna & Boag (1974), Flint *et al.* (1984), Harvey (1990), Inskipp & Inskipp (1993b), Kuz'mina (1992), McClure (1974), Meyer de Schauensee (1984), Potapov & Flint (1989), Robson (1990), Sarker (1986), Smythies (1986), Taka-Tsukasa (1967), Vaurie (1965d), Zeng Yang-zhi & He Fen-qui (1990).

66. Common Quail

Coturnix coturnix

French: Caille des blés **German:** Wachtel **Spanish:** Codorniz Común
Other common names: European/Eurasian (Migratory) Quail (*coturnix*); African Quail (*africana*)

Taxonomy. *Tetrao Coturnix* Linnaeus, 1758, Europe, Asia, Africa = Sweden. Forms superspecies with *C. japonica*, and possibly also with *C. pectoralis*. Internal taxonomy complex and somewhat confused. Present species has been considered to include *C. japonica* as a race, but the two are apparently sympatric in Mongolia. African populations may constitute a separate species, *C. africana*. Birds of E & C Africa often considered to merit subspecific distinction from those in S Africa, and thus awarded race *erlangeri*; this race formerly applied to Ethiopian population only. Birds of S Africa frequently transferred to nominate *coturnix*, as deemed to be inseparable; under such an arrangement, *erlangeri* applied to birds of E & C Africa, and sometimes raised to full species level. Four subspecies recognized.

Subspecies and Distribution.

C. c. coturnix (Linnaeus, 1758) - British Is and NW Africa E to EC Russia and EC India, and possibly to Bangladesh; winters mainly in Sahel zone of Africa and C & S India.

C. c. confisa Hartert, 1917 - Canary Is, Madeira and Azores.

C. c. inopinata Hartert, 1917 - Cape Verde Is.

C. c. africana Temminck & Schlegel, 1849 - sub-Saharan Africa, from Ethiopia and Uganda to S Angola and South Africa (Cape Province), and also Madagascar and Comoros Is; birds from S Africa winter in Angola, S Zaire, N Namibia and W Zambia.

Records from NW Bangladesh normally ascribed to present species (nominate *coturnix*), but perhaps more likely to refer to *C. japonica*. Introduced (*africana*) to Reunion and Mauritius.

Descriptive notes. 16-18 cm, 70-155 g; wingspan 32-35 cm. Usually indistinguishable in the wild from *C. japonica*, except on call; in the hand, differs by having wing over 10.5 cm long, and usually by being less rufous below, from other (*Coturnix*) separated by having outer webs of primaries barred with buff. Female distinguished from *C. japonica* by pattern of underpart feathers

Immature resembles female, but has barred flanks and no lines on lower cheeks. Races vary slightly in size and colour; Palearctic birds larger, paler and greyer, African birds generally smaller, darker and more rufous.

Habitat. Open habitats, including cultivation, in level or gently rolling land; up to 1000 m and much higher in places. Prefers dense herb-herb less than 1 m tall. In NE Tanzania, where breeds alongside *C. delegorguei*, occurs in longer, less degraded grassland. Avoids bare soils.

Food and Feeding. Opportunistic, eating mainly seeds of grasses, weeds and grain, with

well over 100 plant species recorded. Also takes invertebrates from ground, e.g. beetles, bugs, ants, earwigs, grasshoppers, spiders, worms and molluscs.

Breeding. Laying from mid-May to Aug in N Europe, late Mar to mid-June in S Europe; any month in E Africa, but Jan-Feb in Kenya; Sept-Mar in S Africa. Both monogamy and promiscuity reported. Nest is scrape with grass added, constructed by female; sited in herbaceous and grassy cover. Normally 8-13 eggs (4-15) in Europe and 5-7 eggs (2-14) in Africa; incubation 17-20 days, by female only; downy chicks have long blackish stripes on rufous brown upperparts, buffy underparts; chicks can flutter from ground at 11 days; fledging c. 19 days. Young independent after 50-70 days.

Movements. Complex. Majority of W Palearctic breeding birds believed to winter S of Sahara, mainly in Sahel zone, but some winter as far N as British Is and Germany, and with some regularity around Mediterranean; birds of these populations do not seem to cross over equatorial forest; migration routes believed to vary individually, and from year to year. Birds that winter in C & S India believed to migrate through NW Pakistan, before dispersing throughout Indian Subcontinent. S African birds may move N to winter in Angola, S Zaire, N Namibia and W Zambia, where species is probably non-breeding visitor.

Status and Conservation. Not globally threatened. Mace-Landé: Safe. Little information available from which to assess status; problem confounded by occasional and irregular movements in some areas which help to mask long-term trends. Local fluctuations in numbers reported in most areas, with underlying decline in progress in several countries, including parts of France, Netherlands, Germany, Italy, Romania, Ukraine, Russia, Cyprus and Malta, and on most other islands too. Nominate *coturnix* considered abundant to very abundant according to season in some parts of Africa; race *africana* locally abundant. Introduced population on Mauritius only maintained by constant restocking. Hunting of migratory birds is a major problem, especially in parts of Africa; around turn of century, several million birds of nominate *coturnix* were netted in Sinai and other parts of Egypt, when on migration, and hunting still intense; agricultural intensification is possibly also a threat in some areas, especially with increasing use of pesticides. In India, species considered very abundant locally, but numbers vary considerably from year to year; migrants trapped in Pakistan, where species still considered common, but less so than formerly; widely hunted in NW India. Status uncertain in S Arabia: where species is probably only a visitor.

Bibliography. Ali & Ripley (1980), Backhurst *et al.* (1973), Bannerman (1953, 1963), Benson (1960a, 1963), Britton (1980), Cheng Tso-hin (1987), Clancey (1967), Combreau & Guyomarc'h (1989), Courtney-Latimer & Clancey (1960), Cramp & Simmons (1980), Dementiev & Gladkov (1952), Etchécopar & Hue (1978), Flint *et al.* (1984), Gallagher & Woodstock (1980), Gao Jin-hua & Zhang Bing (1984), Ginn *et al.* (1989), Goodman *et al.* (1989), Guyomarc'h (1992), Guyomarc'h *et al.* (1987a, 1987b, 1989, 1990), Holmes (1986), Hudson *et al.* (1985), Inskipp & Inskipp (1985), Jackson & Selator (1978), Kane (1993), Kuz'mina (1992), Langrand (1990), Leveir (1987), Mackworth-Prue & Grant (1957-1973), Maclean (1993), Marchant *et al.* (1990), Meinertzhagen (1954), Mendelssohn *et al.* (1969), Moreau (1963), Moreau & Wayne (1968), Parkes (1993), Paz (1987), Pinto (1983), Potapov & Flint (1989), Puigecerver (1991), Puigecerver *et al.* (1989, 1991), Richardson (1990), Roberts (1991), Rodriguez Teijeiro *et al.* (1992), Rogacheva (1992), Schleidt (1983), Sessions (1967), Simeonov *et al.* (1990), Snow (1978), Urban *et al.* (1986), Vincent (1934).

67. Harlequin Quail

Coturnix delegorguei

French: Caille arlequin **German:** Harlekinwachtel **Spanish:** Codorniz Arlequin

Taxonomy. *Coturnix delegorguei* Delegorgue, 1847, Oury, Upper Limpopo River, Transvaal. Forms superspecies with *C. coromandelica*. Three subspecies recognized.

Subspecies and Distribution.

C. d. arabica Bannerman, 1929 - S Arabia.

C. d. delegorguei Delegorgue, 1847 - Ivory Coast to Ethiopia and S to South Africa (E Cape Province), excluding forest belt and arid SW Africa; apparently only migrant to W Africa.

C. d. histrionica Harlaub, 1849 - São Tomé, Gulf of Guinea.

Descriptive notes. 16-19 cm; male 49-81 g, female 63-94 g. Male has very distinctive combination of black and white head pattern, black breast and chestnut flanks. Female very similar to that of *C. coturnix*, but distinguished in the hand by unbarred outer webs of primaries. Immature resembles female but paler below and on crown. Races differ mainly in tone of plumage coloration.

Habitat. Favours open grassland with scattered bush cover and cultivated areas; also patches of grass in damp situations, e.g. along watercourses. In NE Tanzania, where breeds alongside *C. coturnix*, occurs in shorter, more

degraded grassland.

Food and Feeding. Grass and weed seeds, including *Eleusine*, *Setaria*, *Brachiaria*, *Sorghum*, *Pariplocoeris*, and green shoots; also grasshoppers, beetles, bugs, caterpillars, ants, termites and small ground molluscs.

Breeding. Season associated with heavy rains, irregular with much local variation. Oct-Mar in E South Africa; Jul-Sept in Namibia; Oct-Jun in Zimbabwe; May-Jun and Nov-Dec in Kenya and N

On following pages: 68. Rain Quail (*Coturnix coromandelica*); 69. Stubble Quail (*Coturnix pectoralis*); 70. Brown Quail (*Coturnix ypsilophora*); 71. Asian Blue Quail (*Coturnix chinensis*); 72. African Blue Quail (*Coturnix adansonii*); 73. Snow Mountain Quail (*Anurophasis monorhynx*).

Tanzania: Apr-Jun in Ethiopia; Jul in Sudan; probably all year on São Tomé. Possibly polygynous; sometimes forms loose colonies. Nest is a small scrape with sparse lining, concealed among tufts of grass in grassland. Usually 4-8 eggs; incubation 14-18 days, by female alone; downy chicks have dark brown, black and buff stripes above, buffy yellow underparts; chicks can fly short distances at 5 days.

Movements. Pattern varies according to locality. Nomadic in E & C Africa, movements seemingly associated with rains, but more regular movements may occur in some areas. In S Africa migrates S to breed in rains, and mostly flies N in dry season, but not to same area every year. Situation uncertain in W Africa, where no definite breeding records, and species is probably only a rather irregular migrant: movements in Nigeria particularly confusing, but species is apparently commonest in N during rains, with some southward movement during dry season; dry season migrant to Ivory Coast; only one record each from N Cameroon and Ghana; said to breed in Chad. Various movements reported in other areas.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Little specific information available. Considered to be at least common and even abundant in some areas; no indication that overall numbers are decreasing. Known to be trapped in some areas, e.g. along Kavirondo Gulf (L. Victoria); birds are locally taken for food.

Bibliography. Ash (1992), Backhurst & Pearson (1977), Backhurst *et al.* (1973), Benson (1963), Benson & Benson (1975), Britton (1980), Brown & Britton (1980), Clancey (1967), Elgood (1982), Erlanger (1905, 1907), Ginn *et al.* (1989), Grimés (1987), Hartley & Mundy (1992), Jackson & Slater (1938), Lack (1985), Lack *et al.* (1980), Langrand (1990), Lewis & Pomeroy (1989), Louette (1981), Mackworth-Pratt & Grant (1957-1973), Maclean (1993), Meinhartzen (1954), Milon *et al.* (1973), Pinto (1983), Pomeroy & Abe (1992), Sessions (1967), Urban *et al.* (1986), Vincent (1934).

68. Rain Quail

Coturnix coromandelica

French: Caille natchée **German:** Regenwachtel **Spanish:** Codorniz Coromandélica
Other common names: Black-breasted Quail

Taxonomy. *Tetrao coromandelicus* Gmelin, 1789. Coromandel coast.

Forms superspecies with *C. delegorguei*. Monotypic.

Distribution. Pakistan E to Burma and W Thailand and S through India. Recent record from S Vietnam would extend range to SE considerably.

Descriptive notes. c. 16.5 cm; 64-85 g. Male has distinctive underpart pattern. Female almost indistinguishable in wild from those of three preceding species, but much less distinctly spotted on breast. Young male has less prominent markings on throat and breast.

Habitat. Generally open habitats including grassland, cultivation, dry scrub, meadows and scrub jungle, up to c. 2000 m in the Himalayas.

Food and Feeding. Grass and weed seeds, and insects.

Breeding. Nesting during wet season, generally Mar-Oct, but may vary according to local rainfall. Nest in crops or grass, sometimes in scrub or bush. Lays 4-6 eggs; incubation 18-19 days, by female only.

Movements. Irregular dispersal before breeding in Pakistan where arrives in plains in late Jun, departing from E & S in early Oct. In India, resident and nomadic, or locally migratory during SW monsoon, when moves to areas too dry to inhabit at other times. Occasionally reaches Sri Lanka. Vagrant to Nepal.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Considered safe on the basis of its extensive range and subjective estimates of numbers and trend in some areas. Apparently widespread in grassland and cropland throughout India, where numbers may be stable; in Pakistan considered frequent, although irregular movements make assessment of trends difficult; one recent record from Bangladesh in 1989, where may be very local resident in SE; possibly widespread and under-recorded in Thailand.

Bibliography. Ali & Ripley (1980), Baker (1930), Harvey (1990), Holmes (1986), Inskipp (1989), Inskipp & Inskipp (1985), Kaul & Howman (1991), Lekagul & Round (1991), Ripley (1982), Roberts (1991), Robson *et al.* (1993b), Sankar *et al.* (1993), Sarker (1986), Smythies (1986), Zacharias & Gaston (1993).

69. Stubble Quail

Coturnix pectoralis

French: Caille des chaumes **German:** Schwarzbrustwachtel **Spanish:** Codorniz Pectoral
Other common names: Grey/Pectoral Quail

Taxonomy. *Coturnix pectoralis* Gould, 1837. New South Wales.

Some authors include present species in superspecies formed by *C. coturnix* and *C. japonica*. Sometimes considered race of extinct *C. novaezealandiae* of New Zealand. Monotypic.

Distribution. Australia (mainly in SE & SW); formerly throughout Tasmania, where now very rare, with only three published records since 1977.

Descriptive notes. 16-20 cm; 75-125 g; wingspan 25-33 cm. Male has distinctive brick red face and throat. Female similar to that of *C. coturnix* in size; differs from preceding species by paler and more streaked underparts. Immature male resembles female, but has broader black markings on underparts.

Habitat. Most habitats except forest, especially grassland and well drained cultivation; prefers zones of tall, dense ground vegetation 10-75 cm (preferably 25-50 cm), though also present in areas of low cover, and occasionally even on bare ground, if food abundant. Range can extend into arid zone after rainfall or

flooding.

Food and Feeding. Primarily seeds of grasses, cultivated cereals and weeds; important species are *Avena sativa*, *Hordeum vulgare*, *Lolium perenne*, *Triticum aestivum*, *Polygonum aviculare* and

Cirsium vulgare. Also leaves, buds and flowers of legumes and herbs, and some invertebrates, mainly insects; in several studies, animal items accounted for between 9.3% and 32.3% of total food consumed. Usually forages on the ground, where scratches and gleans, though also climbs wheat stalks to pick seed from heads.

Breeding. Nesting Aug-Mar in most of range, but may vary according to local rainfall pattern. Probably monogamous. Nest is scrape in ground, lined with dried grass, situated in crops or grass. Normally 7-8 eggs (6-14); incubation 18-21 days, by female only; downy chicks are striped ginger brown and black-brown above, pale buff below; young are capable of weak flight at 16 days. Sexual maturity reached at 2-15 months. Breeding success in one study, 26 young reared from 41 eggs laid.

Movements. Most populations nomadic, with opportunistic distribution and reproductive cycles, moving mainly in response to rainfall and food availability. Other populations resident. Irruptions into areas beyond normal range occur occasionally after good rains, especially when numbers have built up during favourable breeding season. Movement of up to 1300 km recorded.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. In Australia, range has expanded and numbers have increased as result of human activities, with species moving into agricultural areas; forest clearance, irrigation and establishment of crops and pastures are all beneficial. In contrast, intensely cultivated or grazed areas are unsuitable for present species. Serious decline in Tasmania, where species almost disappeared by 1953, despite full protection since 1944, coinciding with widespread improvement of pastures. Still present in several islands of Bass Strait, such as Flinders I, where reported to be scarce, and King I, where appears to be common. Suffers considerable hunting pressure, with between 500,000 and 1,000,000 birds shot annually in Victoria during 1930's. Agricultural machinery frequently causes destruction of eggs, young and adults.

Bibliography. Blakers *et al.* (1984), Cruise (1966), Disney (1978), Frith & Carpenter (1980), Frith & Waterman (1977), Frith *et al.* (1977), Macdonald (1988), Marchant & Higgins (1993), McNally (1956), Oliver (1955), Schodde & Tidemann (1988).

70. Brown Quail

Coturnix ypsilophora

French: Caille tasmane **German:** Tasmanienwachtel **Spanish:** Codorniz Tasmana
Other common names: Swamp Quail (*ypsilophora*)

Taxonomy. *Coturnix ypsilophorus* Bosc, 1792, no locality = Tasmania.

Previously placed in genus *Syncoicus*. All races except nominate *ypsilophora* have been considered separate species, *C. australis*, but morphological differences between some of these greater than those between *australis* and *ypsilophora*. Populations of N Queensland, NW Australia and SW Australia have been separated in races *queenslandica*, *cervina* and *sordida* respectively; but differences slight, while there is no clear relation between geographical distribution and colour or pattern of plumage. Ten subspecies normally recognized.

Subspecies and Distribution.

- C. y. raathenii* (S. Müller, 1842) - Lesser Sundas, on Flores, Timor and adjacent islands.
- C. y. pallidior* (Hartert, 1897) - Lesser Sundas, on Sumba and Sawu.
- C. y. saturator* (Hartert, 1930) - lowlands of N New Guinea.
- C. y. lamonti* Mayr & Gilliard, 1954 - moderate heights in mountains of C New Guinea.
- C. y. dogwa* Mayr & Rand, 1937 - lowlands of S New Guinea.
- C. y. plumbeus* (Salvadori, 1894) - lowlands of E New Guinea.
- C. y. monticola* Mayr & Rand, 1937 - alpine areas of SE New Guinea.
- C. y. majulu* Mayr & Rand, 1937 - S slopes of mountains in SE New Guinea.
- C. y. australis* (Latham, 1801) - Australia.
- C. y. ypsilophora* Bosc, 1792 - Tasmania.

Introduced to New Zealand and Fiji.

Descriptive notes. 17-22 cm; 75-140 g; wingspan 26-36 cm. Differs from *C. pectoralis* in barred, not streaked, underparts; larger than *C. chinensis*, smaller and less heavily barred than *Anuophasis monorthonyx*. Female paler overall, with different black markings on upperparts. Immature has more distinct shaft streaks. Races differ mainly in size, and also in colour and pattern of plumage of males; *dogwa* very distinctive, all dark slate.

Habitat. Wet grassland and shrubland, especially in rank grass and moist meadows; also in cereal crops, stubble, coastal scrub, open

woodland and in reedbeds or stands of other dense aquatic vegetation fringing freshwater wetlands; high ground during heavy rainfall. In Australia, prefers well watered areas, but appears far inland, in ephemeral patches of grassland formed after flooding, in years with heavy rains.

Food and Feeding. Mainly seeds of grasses and herbs (*Dactyloctenium*, *Triticum*, *Digitaria*, *Oryza*, *Panicum*, *Stipa*, *Paspalum*, *Lolium*, *Alternanthera*, *Rubus*, *Arctotheca*) and some leaves (*Trifolium*); also some animals, including worms and isopods, a gecko 7.5 cm long, and adults and larvae of insects, e.g. beetles, butterflies and grasshoppers. Forages on ground, gleaning in litter and soil, usually in pairs or small coveys.

Breeding. Season Aug-Jan in S Australia; 2-4 months later in N Australia; Nov-Mar in Tasmania. Monogamous, at least in captivity. Nest is a scrape on the ground, c. 2.5 cm deep, lined with grass and leaves, placed in grass or other dense ground vegetation. Normally 7-11 eggs (up to 14) in Australia, 4-6 in New Guinea; may raise numerous broods in a season; incubation 21-22 days, by female alone; chicks have dark brown and buff down above, dull brown mottled cream below; young capable of flight at 10-17 days.

Movements. Believed to be fairly restricted to wet areas, although may move to high ground during flooding. In Australia, irregularly visits semi-arid and arid districts after good rains have promoted the growth of vegetation. Irruptions beyond normal range occur after favourable breeding seasons.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Little detailed information available. Believed to have suffered with wetland drainage, intensive cultivation, burning of habitat, and increased salinity in some areas, but has benefited in others from increase in extent of stubble fields, irrigation, establishment of pastures and clearance; overall thought to have lost more habitat than has gained, but not considered under threat.

Bibliography. Andrew (1992), Beehler (1978), Beehler *et al.* (1986), Coates (1985), Goodwin (1975), Holmes (1989), Lever (1987), Macdonald (1988), Marchant & Higgins (1993), Mayr (1944), Rand & Gilliard (1967), Schodde & Tidemann (1988), Schönwetter (1967), Westerskov (1985), White & Bruce (1986).

71. Asian Blue Quail

Coturnix chinensis

French: Caille peinte

German: Zwergwachtel

Spanish: Codorniz China

Other common names: King/Painted/Blue-breasted/Chinese Quail

Taxonomy. *Tetrao chinensis* Linnaeus, 1766. China and the Philippines = Nanking, China. Previously placed in genus *Excalfactoria*. Sometimes considered conspecific with *C. adansonii*, with which forms superspecies. As consequence of transfer of present species from *Excalfactoria* to *Coturnix*, subspecies name *australis* preoccupied by *C. psilophora australis*, so gives place to junior synonym *victoriae*. Ten subspecies recognized.

Subspecies and Distribution.

C. c. chinensis (Linnaeus, 1766) - India and Sri Lanka E through Indochina to SE China and Taiwan, and S to Malay Peninsula.

C. c. trinkuensis (Richmond, 1902) - Nicobar Is; also said to occur in Andaman Is (race unspecified).

C. c. palmeri (Riley, 1919) - Sumatra and Java.

C. c. lineata (Scopoli, 1786) - Philippines, Borneo and Sulawesi.

C. c. lineatula (Rensch, 1931) - Lombok E to Timor, Lesser Sundaes.

C. c. novaeguineae Rand, 1942 - mountains of New Guinea.

C. c. papuensis Mayr & Rand, 1937 - SE New Guinea.

C. c. lepida (Hartlaub, 1879) - Bismarck Archipelago.

C. c. collettii (Mathews, 1912) - Northern Territory, Australia.

C. c. victoriae (Mathews, 1912) - E Australia.

Introduced to Guam and SE Australia.

Descriptive notes. 12-15 cm; 20-57 g; wing-span c. 25 cm. Male very distinctive, differs from similar *C. adansonii* in chestnut belly and lack of chestnut wing patch. Female differs from that of *C. psilophora* by smaller size, and from that of similar *C. adansonii* by less distinct barring on upperwing-coverts. Immature male similar to adult female, but has more conspicuous black and buff markings above; immature female as adult, but with more spotted, less barred underparts. Races separated partly on darkness of plumage.

Habitat. Dense grassland, shrubland, swamp edges, cultivation with unkept areas and de-

pleted woodland; chiefly found in plains, but up to 2000 m in suitable habitat in India.

Food and Feeding. Apparently mainly grass seeds, green blades and some insects (especially termites), both adults and larvae. Forages on the ground, gleaning and scratching in litter.

Breeding. Season probably related to rainfall patterns: Sept-Mar in S Australia; Feb-Apr in N Australia; Jan-Aug in Peninsular Malaysia; Jun-Aug in NE India; Mar-Apr in S India. Monogamous, at any rate in captivity. Nest is depression on ground lined with dry grass. Normally 4-7 (up to 9) eggs; incubation 16-18 days, by female only; chicks have ginger brown down above with bold blackish stripes, buff below; young capable of flight at 4 weeks. Sexual maturity reached at 3 months.

Movements. In India, nomadic or migratory, for breeding moving to areas where rains have ended. Generally encountered in coveys of 6-7 birds, although up to 40 seen together. In Malay Peninsula, no evidence of regular migration, but species moves long distances, at least occasionally at night; similar movements recorded in Burma and Philippines.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Little detailed information available. Very widespread, but little recorded in most parts of range, although considered common in Malaysia. In India, considered sparsely distributed in small numbers over large areas; no recent records from Bangladesh. Considered safe because of extensive range, but more information clearly required on current status in all areas. Apparently erratic movements hamper status assessments.

Bibliography. Ali & Ripley (1980), Baker (1935), Chasen (1939), Cheng Tso-hun (1987), Coates (1985), Coomans de Ruiter (1946), Deignan (1945), Dickinson *et al.* (1991), Etchécopar & Hue (1978), Evans *et al.* (1993), Gibson-Hill (1949, 1952), Grimes (1987), Harrison (1965), Harvey (1990), Holmes (1989), Holmes & Burton (1987), Inskipp (1989), Inskipp & Inskipp (1985), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Phillips (1993), Mann (1987), Marchant & Higgins (1993), van Marle & Voous (1988), Medway & Wells (1976), Robinson & Chasen (1936), Robinson & Kloss (1921, 1924), Robson, Eames *et al.* (1993a, 1993b), Robson, Eames, Wolstencroft *et al.* (1989), Sankar *et al.* (1993), Sarker (1986), Schleidt *et al.* (1984), Schodde & Tidemann (1988), Smythies (1957, 1981, 1986), Zacharias & Gaston (1993).

72. African Blue Quail

Coturnix adansonii

French: Caille bleue

German: Adonsonwachtel

Spanish: Codorniz Africana

Other common names: Blue/King Quail

Taxonomy. *Coturnix Adansonii* J. and E. Verreaux, 1851. Gabon.

Formerly placed in genus *Excalfactoria*; sometimes considered a race of *C. chinensis*, with which forms superspecies. Monotypic.

Distribution. Sub-Saharan Africa, from Sierra Leone and S Mali E to S Ethiopia and NW Kenya, and S to Angola, Zimbabwe and E South Africa; not in W African forests or C Tanzania.

Descriptive notes. 15 cm; 43-46.6 g. Male differs from that of *C. chinensis* by chestnut wing-patch and flanks, and slaty belly. Female differs from that of *C. chinensis* by more distinct barring on upperwing-coverts; from other *Coturnix* females by small size and heavily barred underparts. Immature resembles female but has distinct pale shaft streaks on upperwing, rump and uppertail-coverts.

Habitat. Dense grassy habitats, such as thick grass along watercourses and swamps, and borders of cultivation; also occurs on granite outcrops in Sierra Leone. In Kenya, occurs in wetter grassland than *C. delegorguei*.

Food and Feeding. Grass and weed seeds, green plant matter, termites and other insects.

Breeding. Season is during or soon after rains: Nov and May-Jun in Cameroon; Apr-Jun in Uganda; Oct-Nov and May-Jul in Kenya; Feb-Jun in Malawi; Jan-Feb in Zambia; Jan-Apr in Zimbabwe; Dec-Apr in South Africa. Nest is a small scrape on ground below grass tussock, sometimes lined with grass. Lays 3-9 eggs; incubation c. 16 days, by female only.

Movements. Poorly known, but local movements reported in some areas, especially in W Africa, where apparently related to rains: in Ivory Coast, occurs in savanna N from coast mainly during Nov-May, in dry season; in Ghana, mostly recorded during rains, May-Jul, but during dry season in coastal areas; in Sierra Leone, where probably non-breeding migrant, present Nov-Jun, with both number of records and size of coveys peaking in Mar-May; arrives near Lagos, S Nigeria, in late Mar, during peak of rains, departing after breeding. In South Africa, may breed in summer, moving N in winter.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Little detailed information available. Very widespread species, considered to be local and uncommon in most areas. Widespread in C Angola, Zambia and Malawi, but sparsely distributed throughout most of range, absent where too dry, and fairly localized in Zimbabwe, Mozambique and E South Africa.

Bibliography. Ash (1992), Bannerman (1910, 1949, 1953), Benson (1963), Benson & Benson (1975), Britton (1980), Brown & Britton (1980), Clancey (1967), Ginn *et al.* (1989), Grimes (1987), Jackson (1911), Jackson & Selater (1938), Jones, M.A. (1979), Lewis & Pomeroy (1989), Louette (1981), Mackworth-Praed & Grant (1957-1973), Maclean (1993), Nikolaus (1987), Pakenham (1979), Pinto (1983), Prigione (1985), Serle (1981), Snow (1978), van Someren (1925-1935), Urban *et al.* (1986).

Genus ANUROPHASIS van Oort, 1910

73. Snow Mountain Quail

Anurophasis monorthonyx

French: Caille de montagne

German: Schneegebirgswachtel

Spanish: Codorniz Papúa

Other common names: New Guinea Quail

Taxonomy. *Anurophasis monorthonyx* van Oort, 1910, at 3800 metres, Oranje (Snow) Mountains, New Guinea.

Has been included in genus *Coturnix*. Monotypic.

Distribution. Kemabu Plateau, and Mt Wilhelm and Mt Carstenz (Snow Mts), Irian Jaya, W New Guinea.

Descriptive notes. c. 25-28 cm; c. 401 g. Distinctive combination of large size and blackish barring above and below. Female paler, less rufous. Immature resembles adult, but with more irregular and less distinct barring.

Habitat. Found in alpine grassland and at edges of alpine scrub, on N slopes between 3100 m and 4000 m.

Food and Feeding. Flower heads, leaves, seeds and caterpillars reported.

Breeding. Only information is 3 eggs in a nest beside a grass tussock in Sept.

Movements. No information available.

Status and Conservation. Not globally

threatened. Mace-Lande: Safe. Currently considered near-threatened. Not protected by Indonesian law, but considered safe because of remote distribution in Snow Mts; very few records since late 1930's. Numbers probably low, given small range; occurs in Central New Guinean High Mountains Endemic Bird Area. Very low encounter rate makes direct assessment of trend impossible; population assumed to be stable, again because of occurrence in remote, generally inaccessible areas. Survey work in suitable habitat clearly needed.

Genus *PERDICULA* Hodgson, 1837

74. Jungle Bush-quail

Perdicula asiatica

French: *Pardicula rousse-gorge* German: *Dschungelwachtel* Spanish: *Pardicilla Golirroja*

Taxonomy. *Perdicula asiatica* Latham, 1790, Mahratta region, India. Four subspecies recognized.

Subspecies and Distribution.

P. a. punjaubi Whistler, 1939 - NW India, from Kashmir to Uttar Pradesh.

P. a. vidali Whistler & Kinnear, 1936 - W India.

P. a. asiatica (Latham, 1790) - C & NE India, from Gujarat to Bihar.

P. a. ceylonensis Whistler & Kinnear, 1936 - Sri Lanka.

Introduced population on Reunion may still exist.

Descriptive notes. c. 15-18 cm; c. 57-82 g. Outermost primary longer than innermost, and inner webs of primaries brown, usually diagnostic; differs from *P. argoondah* by colour pattern of eyestripe and throat. Immature paler, with broader buffy stripes on upperparts. Races separated on coloration of upperpart plumage.

Habitat. Dry scrub and brush habitats, often stony, ranging from thin grass to fairly dense deciduous forests; recorded up to 1200 m.

Food and Feeding. Very little information available. Feeds on seeds, including those of grass, herbs, gram and millet, and some insects.

Breeding. End of rains to end of cold season: Jan-Mar in Karnataka, Oct-Mar in Deccan, Mar-Apr in EC India and Sri Lanka. Nest situated in cover. Lays 5-6 eggs (4-8); incubation 16-18 days (21 in captivity), by female alone; chicks have chestnut and dark brown down above, ochraceous grey below.

Movements. No information available; probably sedentary, but thought to be migrant in Nepal. Coveys tend to sit tight, "exploding" into flight when pressed.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Considered safe because of extensive range and occurrence at edges of agricultural land, although not believed to enter standing crops. Little information available on abundance and trends. Distributed throughout India, and has been collected in Nepal; was plentiful in parts of Sri Lanka until 1950's at least.

Bibliography. Alderton (1992), Ali (1979), Ali & Ripley (1980), Baker (1930, 1935), Crowe & Crowe (1985), Henry (1971), Inskipp & Inskipp (1985), Johnsgard (1988), Kaul & Howman (1991), Phillips (1978), Ripley (1982), Sankar et al. (1993), Thornhill (1981).

75. Rock Bush-quail

Perdicula argoondah

French: *Pardicula argoondah* German: *Madraswachtel* Spanish: *Pardicilla Argundá*

Taxonomy. *Coturnix Argoondah* Sykes, 1832, Deccan.

Race *salimalii* has been considered a mere morph. Three subspecies recognized.

Subspecies and Distribution.

P. a. meinertzhageni Whistler, 1937 - NW India S to Kutch and E to W Madhya Pradesh.

P. a. argoondah (Sykes, 1832) - Peninsular India.

P. a. salimalii Whistler, 1943 - S India (EC Karnataka).

Descriptive notes. c. 15-18 cm; 59-74 g. Outermost primary longer than innermost, and inner webs of primaries mottled or barred buff, usually diagnostic; differs from *P. asiatica* by colour pattern of eyestripe and throat. Immature resembles male in having blackish bars, unlike immature *P. asiatica*. Race *meinertzhageni* has paler upperparts; *salimalii* has brick red upperparts.

Habitat. Semi-desert habitats such as dry, open plains littered with thorny bushes; rarely occurs above 600 m.

Food and Feeding. No information available.

Breeding. Seasonality uncertain, but possibly

related to rainfall; generally Aug-Nov and Jan-Mar. Nest situated under a rock or in cover. Lays 5-6 eggs (4-8); incubation 16-18 days, by female alone; chicks have earthy brown down above barred black, fulvous buff below more or less barred blackish brown.

Movements. No information available; probably sedentary. Coveys tend to sit tight, "exploding" into flight when pressed.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Considered to be safe from extinction because of extensive range and fact that species appears to be rather common in scrubby habitats. No information available on numbers and trends. Habitat is being damaged, lost to urbanization and degraded; species is also hunted for food.

Bibliography. Alderton (1992), Ali & Ripley (1980), Baker (1930, 1935), Johnsgard (1988), Raethel (1988), Ripley (1982), Robbins (1981), Zacharias & Gaston (1993).

76. Painted Bush-quail

Perdicula erythrorhyncha

French: *Pardicula à bec rouge* German: *Buntwachtel* Spanish: *Pardicilla Piquirroja*

Taxonomy. *Coturnix erythrorhyncha* Sykes, 1832, Karli Valley, north Konkan. Has been included in genus *Cryptoplectron*. Two subspecies recognized.

Subspecies and Distribution.

P. e. erythrorhyncha (Sykes, 1832) - W Ghats of W India.

P. e. blewitti (Hume, 1874) - C & E India.

Descriptive notes. Nominate *erythrorhyncha* c. 18 cm, 70-85 g; race *blewitti* c. 16 cm, 50-70 g. Outermost primary equal to innermost, and upperparts brown with black spots, diagnostic in combination. Female resembles male but for head pattern. Immature male has less prominent head markings; immature female has blackish crown. Race *blewitti* smaller and paler.

Habitat. Grassland and scrub, forest edge and cultivation; from 600 m to 2000 m.

Food and Feeding. Seeds of grasses and weeds, green plant matter, and termites and other insects.

Breeding. Season poorly defined and nests found in most months, varying according to locality. Nest apparently ill concealed amidst cover and sometimes lined with grass. Lays 4-7 eggs (up to 10); incubation 16-18 days, by female only.

Movements. No information available; probably sedentary. Moves out to feed in more open patches in morning and evening. Coveys tend to sit tight; when pressed, birds fly short distances in different directions.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Considered to be safe because of extensive range and also due to occurrence on margins of agricultural land and in forest edge habitat. No information available on either relative abundance or trends; no specific threats identified to date.

Bibliography. Alderton (1992), Ali (1979), Ali & Ripley (1980), Baker (1930, 1935), Johnsgard (1988), Raethel (1988), Ripley (1982), Robbins (1981), Zacharias & Gaston (1993).

77. Manipur Bush-quail

Perdicula manipurensis

French: *Pardicula de Manipur* German: *Manipurwachtel* Spanish: *Pardicilla de Manipur*
Other common names: Assam Bush-quail

Taxonomy. *Perdicula manipurensis* Hume, 1880, bases of hills in south-eastern Manipur Plain. Has been included in genus *Cryptoplectron*. Two subspecies recognized.

Subspecies and Distribution.

P. m. manipurensis Hume, 1880 - NE India (in hills of Manipur and Assam S of R Brahmaputra) and Bangladesh.

P. m. inglisti (Ogilvie-Grant, 1909) - NE India (in West Bengal and Assam N of R Brahmaputra).

Descriptive notes. c. 19 cm; 64-78 g. Outermost primary equal in length to innermost, and upperparts slaty grey, diagnostic in combination. Immature browner than adult, with heavier black markings. Race *inglisti* has upperparts more faintly marked with black.

Habitat. Very specific habitat requirement: tall, dense grassland, especially of elephant grass, up to c. 1000 m; sometimes around swamps.

Food and Feeding. Seeds of grasses and herbs, pods and some insects.

Breeding. Only one nest reported (*manipurensis*), which had 4 eggs in a hollow scraped in ground among grass roots in May.

Adults (*inglisti*) show signs of breeding at beginning of Mar.

Movements. No information available; probably sedentary. Moves out to feed in burnt grass patches in early morning and afternoon. Flies a short distance when pressed.

Status and Conservation. RARE. Mace-Lande: Endangered. Considered threatened because of very small range and highly fragmented habitat; must be declining in numbers. No recent records from Bangladesh, where few, if any, extensive areas of elephant grass remain, and those that survive are flooded for two thirds of the year; species may, however, still occur in Chittagong Hill Tracts. During late 1940's, it was thought that species might yet prove to inhabit the Chindwin Valley of Burma, but this remains a mere possibility. Species occurs in Assam Plains Endemic Bird Area. Threatened by continuing loss and fragmentation of habitat and some overhunting. An extensive survey is clearly required, concentrating on all known localities, past and present.

Bibliography. Alderton (1992), Ali & Ripley (1980), Baker (1930), Collar & Andrew (1988), Harvey (1990), Johnsgard (1988), Raethel (1988), Ripley (1982), Robbins (1981), Schonwetter (1967), Smythies (1986).

Genus *OPHRYSIA* Bonaparte, 1856

78. Himalayan Quail

Ophrysia superciliosa

French: *Ophrysie de l'Himalaya* German: *Himalayawachtel* Spanish: *Pardicilla Himalaya*
Other common names: Indian/Mountain Quail

Taxonomy. *Rollulus superciliosus* J. E. Gray, 1846, India = Mussoorie. Monotypic.

Distribution. N India: known only from areas around Mussoorie and Naini Tal in Uttar Pradesh. Possibly extinct.

Descriptive notes. c. 25 cm. Long tail and bristle-like feathers on forehead; small white patches in front of and behind eye; body feathers have unusual shape and texture. Female shows distinctive combination of red bill and mostly tawny to cinnamon brown plumage heavily patterned with blackish spots and streaks.

Habitat. Occurs, or occurred, on steep hill-sides, in patches of long grass and brushwood; recorded from c. 1650 m up to c. 2100 m.

Food and Feeding. Grass seeds recorded; probably also berries and insects.

Breeding. No information available.

Movements. No reliable information available. Stated to be a poor flier, covering only short distances when almost stepped upon; contrary to this, however, it has been suggested that the species wintered in N India, moving down from possible breeding grounds farther N. Occurred in coveys of 5-6 birds.

Status and Conservation. Almost certainly EXTINCT. Mace-Lande: Critical/Extinct. Only known from 9-10 specimens, the last of which was collected over 100 years ago. Restricted range; range falls within Western Himalaya Endemic Bird Area. Species possibly very difficult to locate; over last 40 years, there have been several unconfirmed records from the region, but despite various efforts, there is no proof that species survives. Causes of presumed decline and possible extirpation of species remain unknown. A survey of (former) localities is required at appropriate time of year, in attempt to establish whether or not species is still extant; this should include interviews with local human population.

Bibliography. Alderton (1992), Ali (1977, 1979), Ali & Ripley (1980), Baker (1930), Collar & Andrew (1988), Johnsgard (1988), Kaul (1992), Mukherjee (1966), Negi (1992), Raethel (1988), Rieger & Walzhöny (1992), Ripley (1952, 1982), Robbins (1981), Sankaran (1990).

Genus *XENOPERDIX* Dinesen *et al.*, 1994

79. Udzungwa Forest-partridge

Xenoperdix udzungwensis

French: Xénoperdrix de Tanzanie German: Udzungwawachtel Spanish: Perdiz de Udzungwa

Taxonomy. *Xenoperdix udzungwensis* Dinesen *et al.*, 1994, Ndundulu Mountains, in Udzungwa Mountains, Tanzania.

Originally thought to be an aberrant species of forest francolin, but extensive taxonomic study indicates that present species is probably most closely related to the Asiatic genus *Arborophila*; significant similarities include pattern of underwing-coverts, scaling on rear part of tarsus, several general plumage features, tree-roosting habit and whistling calls. Monotypic.

Distribution. S Tanzania, where occurs in two areas within Udzungwa Mts: Ndundulu Mts and Nyumbanitu Mts.

Descriptive notes. c. 29 cm; 3 males 220 g, 222 g and 239 g. Bright red bill, strongly barred upperparts and heavily blotched underparts. Female very similar to male, but (on limited material) has darker crown, more extensive blotching on underparts and larger dark patch on face. Immature undescribed.

Habitat. Montane and submontane evergreen forest between 1350 m and 1900 m; seen on ridges and steep slopes, and also on flatter ground, especially where understory open.

Food and Feeding. Invertebrates such as beetles, ants, flies and woodlice; also seeds. Feeds among leaf litter on forest floor by

scratching and turning over leaves with bill; also picks at low herbs, possibly for insects.

Breeding. Possibly from onset of rains: adult seen with chicks in late Nov and again in early Dec. No further information available.

Movements. No information available.

Status and Conservation. VULNERABLE. Mace-Lande: Vulnerable. Considered vulnerable mainly because of limited range; total known range less than 300 km²; site in Ndundulu Mts is W part of a forest covering 240 km², site in Nyumbanitu Mts covers 55 km². Species discovered after completion of Biodiversity Project; occurs in Eastern Arc Mountains Endemic Bird Area. Frequently encountered; flocks of up to 8 recorded and a total of 246 individuals seen in 85 encounters during 5½ months of fieldwork in 1991-1992. However, recent survey of one of the sites failed to find species, and reported widespread snaring. Ndundulu and Nyumbanitu Mts are within West Kilombero Scarp Forest Reserve; other parts of which are included in Udzungwa Mountains National Park, gazetted in Feb 1992; distribution of species within this park not yet known. Limited distribution makes species vulnerable to habitat alterations.

Bibliography. Anon. (1994), Dinesen *et al.* (1994).

Genus *ARBOROPHILA* Hodgson, 1837

80. Common Hill-partridge

Arborophila torquedula

French: Torquéole à collier

German: Hügelhuhn

Spanish: Arborófila Común

Other common names: Hill Partridge, Necklaced/Indian Hill-partridge

Taxonomy. *Perdix torquedula* Valenciennes, 1826, Bengal.

Four subspecies recognized.

Subspecies and Distribution.

A. t. millardi (Stuart Baker, 1921) - W Himalayas.

A. t. torquedula (Valenciennes, 1826) - Nepal E to Tibet and N Burma.

A. t. batemani (Ogilvie-Grant, 1906) - N Burma and SC China (W Yunnan, SW Sichuan).

A. t. griseata Delacour & Jabouille, 1930 - NW Vietnam.

Descriptive notes. c. 29 cm; 227-430 g. Head pattern distinctive. Female differs mainly on crown and throat; lacks male's head pattern and neck band. Immature male resembles adult, but lacks eyestripe, and has underparts spotted white. Races separated on neck and underpart patterns.

Habitat. Evergreen forest and scrub, usually between 1500 m and 2700 m, but higher in some areas; occurs in particularly heavy hill forest with streams and dense undergrowth.

Food and Feeding. Seeds, shoots, berries, insects and small molluscs. Scratches for food amongst leaf litter.

Breeding. Season Apr-Jul in India, earlier at lower altitudes; Feb-May in race *batemani*. Nest varies from a scrape to a deep cup, lined with grass; one nest of race *millardi* was in a hole scraped out in a bank, domed over with grass. Lays 3-5 eggs (up to 9); incubation apparently 24 days, in captivity; chicks have chestnut and dark brown down on upperparts, pale buff underparts, with a dark brown band on breast.

Movements. No altitudinal movements reported. Prefers to escape by running, but if flushed flies strongly between trees.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Considered fairly common in Nepal. No information on abundance or trends in India, other than that species was reported to be fairly common in Sikkim in 1960's, and likely to be stable in Bhutan. Very common in Burma in late 1940's; considered rare in China. No information available on actual or potential threats, but species probably declining due to habitat loss and degradation; unlikely to be threatened in Bhutan.

Bibliography. Ali (1962), Ali & Ripley (1980), Baker (1930), Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Davison (1982a), Eichécopar & Hüc (1978), Gaston *et al.* (1993), He Fen-qi *et al.* (1990), Inskipp & Inskipp (1985, 1993a, 1993b), Johnsgard (1988), Katti *et al.* (1992), Kaul & Ahmed (1993), Meyer de Schauensee (1984), Robson (1986), Smythies (1986), Tymstra (1993).

81. Sichuan Hill-partridge

Arborophila rufipectus

French: Torquéole de Boulton

German: Boultonbuschwachtel

Spanish: Arborófila de Sichuan

Other common names: Boulton's Hill-partridge, Sichuan Partridge

Taxonomy. *Arborophila rufipectus* Boulton, 1932, west Sichuan, China.

Sometimes included in proposed superspecies formed by *A. javanica*, *A. orientalis* and *A. brunneopectus*. Monotypic.

Distribution. SC China (S Sichuan, and perhaps also NE Yunnan).

Descriptive notes. 28-30.5 cm; male 410-470 g, female 350-380 g. Distinguished from *A. torquedula* by mainly white throat and russet on breast. Female duller. Immature undescribed.

Habitat. Subtropical evergreen forest and woods, usually between 1000 m and 2000 m.

Food and Feeding. Fruits of *Elaeagnus*, *Eunonymus*, *Rubus* and oaks reported; also some invertebrates.

Breeding. Season Apr-Jun. Nest is a scrape, usually among tree roots. Lays 5-6 eggs. No further information available.

Movements. No information available.

Status and Conservation. ENDANGERED. Mace-Lande: Critical. One of the most threatened of all Galliformes; population estimated at c. 1000 birds, and currently declining, although still said to be locally common; known from five sites in overall area of under 100 km². Not found in any protected area within its tiny range; occurs in South China Forests Endemic Bird Area. Logging is causing both loss and degradation of its habitat, and artificial replanting, especially with monocultures, is also reducing extent of suitable habitat available to species.

Bibliography. Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Collar & Andrew (1988), Davison (1982a), Eichécopar & Hüc (1978), He Fen-qi (1992), Johnsgard (1988), King, B.F. (1989a, 1989b), Li Gui-yuan *et al.* (1974), McGowan (1994a), Meyer de Schauensee (1984), Raethel (1988).

82. Chestnut-breasted Hill-partridge

Arborophila mandellii

French: Torquéole de Mandell

Spanish: Arborófila Pechirroja

German: Rothrust-Buschwachtel

Other common names: Red-breasted Hill-partridge, Chestnut-breasted Partridge

Taxonomy. *Arborophila Mandellii* Hume, 1874, Bhutan Duars.

Monotypic.

Distribution. NE India (Arunachal Pradesh and Sikkim) through Bhutan to SE Tibet.

Descriptive notes. c. 28 cm; c. 268 g. Bright pattern on head and neck distinctive. Immature undescribed.

Habitat. Believed to inhabit evergreen forest undergrowth at 350-2500 m.

Food and Feeding. No information available.

Breeding. Believed to be Mar-Jun in Tibet. One nest reported, 4 eggs in oak/rhododendron forest at 2400 m in Sikkim.

Movements. No altitudinal movement reported.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. Currently considered near-threatened. Very little information available on status in wild; only recent records are from 2-3 sites in Arunachal Pradesh, and some possible records from Bhutan. Status inferred from condition of habitat, which may always have been fragmented throughout its limited range; occurs in Eastern Himalaya Endemic Bird Area. Threats are mainly pressures on presumed habitat, through felling of trees and slash-and-burn agriculture; hunting for food may be a problem in some areas. Survey work is clearly required.

Bibliography. Ali (1962), Ali & Ripley (1980), Baker (1930), Cheng Tso-hin (1987), Davison (1982a), Inskipp & Inskipp (1993b), Johnsgard (1988), Meyer de Schauensee (1984), Raethel (1988), Ripley (1982), Smythies (1986).

83. Collared Hill-partridge

Arborophila gingica

French: Torquéole de Gingi **German:** Chinabuschwachtel **Spanish:** Arborófila de Fujián
Other common names: White-necklaced/Rickett's/Fokien Hill-partridge, Rickett's Partridge

Taxonomy. *Tetrao gingicus* Gmelin, 1789, "Gingi in Coromandel"; error = south-east China. Monotypic.

Distribution. SE China, from SW Zhejiang S to Guangdong and E Guangxi.

Descriptive notes. c. 25-30 cm; one individual 253 g. Striking head pattern; combination of black, white and chestnut bands across upper breast separates from all congeners. Female somewhat smaller; resembles male but has chestnut and white undertail-coverts. Immature has greyer eyestripe.

Habitat. Dense broad-leaved and mixed broad-leaved and coniferous forests in hills and mountains, occurring at 500-1700 m.

Food and Feeding. Seeds, berries and insects reported.

Breeding. Probably lays Apr-May; 5-7 eggs. **Movements.** No information available.

Status and Conservation. RARE. Mace-Lande: Endangered. Little detailed information available, but still said to be locally common; occurs in several protected areas; logging is fragmenting and reducing extent of suitable habitat, and population now probably numbers fewer than 10,000 individuals; currently considered rare throughout most of range, which has a dense human population. Species has restricted range; occurs in Fujian Mountains Endemic Bird Area.

Bibliography. Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Collar & Andrew (1988), Davison (1982a), Eichécopar & Hùe (1978), Hui, Ming & Tian (1993), Johnsgard (1988), Kang (1969), Li Xiao-Hui *et al.* (1990, 1992), Meyer de Schauensee (1984), Raethel (1988).

84. Rufous-throated Hill-partridge

Arborophila rufogularis

French: Torquéole à gorge rousse

German: Rotkehl-Buschwachtel

Spanish: Arborófila Golirufa

Other common names: Rufous-throated Partridge

Taxonomy. *Arboricola rufogularis* Blyth, 1850, Darjeeling, north-east India.

Proposed race *laotiana* not generally accepted; instead included within race *guttata*. Six subspecies normally recognized.

Subspecies and Distribution.

A. r. rufogularis (Blyth, 1850) - N India (from Uttar Pradesh E to Assam) and Nepal.

A. r. intermedia (Blyth, 1856) - NE India (Assam S of R Brahmaputra) E to Burma (Arrakan Yomas).

A. r. tickelli (Hume, 1880) - E & S Burma (from South Shan to Tenasserim) E to Thailand and SW Laos.

A. r. euroa (Bangs & Phillips, 1914) - SC China (SE Yunnan) to N Laos.

A. r. guttata Delacour & Jabouille, 1928 - C Vietnam.

A. r. annamensis (Robinson & Kloss, 1919) - SC Vietnam.

Descriptive notes. c. 28 cm; 200-300 g (*rufogularis*), 340-370 g (males of *intermedia*). Head and throat pattern distinctive. Female rather similar to male, but has less black on chin and throat, and more white spots on underparts; crown browner. Immature duller, with more white spots below. Races vary most conspicuously in head and throat pattern.

Habitat. Occurs in evergreen forest with thick undergrowth, from 300 m up to 2600 m; also found in areas of bamboo, scrub and heavy secondary growth.

Food and Feeding. Seeds, berries, green plant matter and invertebrates reported.

Breeding. Season Apr-Aug, mainly May-Jun. Nest is either simply a scrape, or can have a dome of grass and a small entrance hole; in both cases, sited in grass. Lays 4-5 eggs (up to 8); incubation c. 20-21 days; chicks have chocolate brown down above, brownish cream below, with dark breast and flanks.

Movements. No altitudinal movement reported. Prefers to escape from potential danger by running, rather than flying.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Considered safe mainly because of large range, but situation may be more serious than currently believed. Species is scarce resident in Nepal, where numbers are declining such that it is considered in danger of extinction in this country. In India, no recent information, but both *rufogularis* and *intermedia* were formerly considered locally common. Widely distributed in Burma up to 1940's at least, but rare below 900 m and absent or very rare in many areas. No recent records from Bangladesh where may formerly have been resident; may still occur in hill forest in Chittagong Hill Tracts of NE. Probably still widespread but scarce in much of N Thailand. Main threats are those to habitat, e.g. in Nepal and Thailand; overhunting also believed to be a problem throughout much of range.

Bibliography. Ali & Ripley (1980), Baker (1928, 1930), Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Davison (1982a), Deignan (1945), Etchécopar & Hùe (1978), Harvey (1990), Inskipp (1989), Inskipp & Inskipp (1985, 1993b), Johnsgard (1988), Lekagul & Round (1991), Meyer de Schauensee (1984), Robson *et al.* (1993a, 1993b), Round (1988), Sarker (1986), Smythies (1986), Tang Chan-zhu (1990).

85. White-cheeked Hill-partridge

Arborophila atrogularis

French: Torquéole à joues blanches

German: Wei Wangen-Buschwachtel

Spanish: Arborófila Cariblanca

Other common names: White-cheeked Partridge

Taxonomy. *Arboricola atrogularis* Blyth, 1850, Assam, Sylhet and Arrakan.

Monotypic.

Distribution. NE India (Assam), Bangladesh, N Burma and SC China (W Yunnan).

Descriptive notes. c. 28 cm; 200-312 g. Distinctive head and neck pattern distinguishes from most congeners; grey and brown crown separates from some similar forms of *A. orientalis*. Female generally similar to male, but has yellower tarsus. Immature apparently undescribed.

Habitat. Occurs from foothills up to 1500 m in evergreen forest, scrub and bamboo; even found in grassland and cultivation adjacent to forest cover.

Food and Feeding. Very little information available. Believed to feed on seeds of weeds, as well as berries, shoots and assorted invertebrates.

tebrates.

Breeding. Laying Mar-Apr in India at lower altitudes, Jun-Jul higher up; timing of season not known elsewhere. Nest is a scrape situated under scrub in grassland or bamboo, usually lined with grass and leaves. Usually 4-5 eggs (3-7).

Movements. No information on any seasonal movements, but species may well be simply rare visitor to Bangladesh. When a covey is pressed, birds flush one at a time.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Currently considered near-threatened. Considered safe mainly because of fairly large range, but situation may be more serious than is anticipated at present. In India, no recent information, but formerly considered to be commoner

at lower altitudes, which may now be more disturbed. Several records from estates in NE Bangladesh, but now believed only rare visitor where once was more frequent; may still occur in SE hill forest. Common in foothills below 1300 m in Burma up to 1940's at least, but no recent information. Quite rare within its very small range in SC China. Main threats are to its habitat, especially as it inhabits lower slopes of hills. More detailed and up-to-date information is required on this species.

Bibliography. Ali & Ripley (1980), Baker (1930), Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Davison (1982a), Harvey (1990), Johnsgard (1988), Meyer de Schauensee (1984), Morioka (1957), Ræthel (1988), Ripley (1982), Sarker (1986), Smythies (1986).

86. Taiwan Hill-partridge

Arborophila crudigularis

French: Torquéole de Formose

German: Taiwanbuschwachtel

Spanish: Arborófila de Formosa

Other common names: Formosan Hill-partridge, Taiwan Partridge

Taxonomy. *Oreoperdix crudigularis* Swinhoe, 1864, mountains of Taiwan.

Monotypic.

Distribution. Mountains of Taiwan.

Descriptive notes. c. 28 cm; one male 311 g, female c. 212 g. Distinctive head and neck pattern, showing more extensive white on face than most other *Arborophila* that have grey underparts; similar to some forms of *A. orientalis*, but always has paler crown, and tends to be more boldly marked on upperparts. Female has more white spotting below, especially on flanks, and fewer black markings on throat. Immature plumage apparently undescribed.

Habitat. Temperate primary broad-leaved and possibly mixed forest between 1500 m and 2000 m.

Food and Feeding. Seeds, berries, seedlings,

leaves and invertebrates reported.

Breeding. Season from late Feb to Aug. Nest situated in crevice amongst boulders, or hidden at base of tree. Lays 6-8 eggs; incubation reported to last 24 days, but only 20-21 in captivity.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. Formerly widespread at suitable altitudes, but few records in recent years. Overall population likely to number less than 10,000 birds; species declining outside protected areas, but probably stable within them. Known from Taroko, Hsieh-Ba and Yushan National Parks, Yu-Li, Chu-yun Shan, Nanao Lake and Hardwood and Tsuifeng Lake Wildlife Nature Reserves. Species has restricted range; occurs in Taiwan Endemic Bird Area. Main pressures are those on habitat, which is in process of being reduced by tree-felling and conversion to agricultural land.

Bibliography. Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Davison (1982a), Etchécopar & Hue (1978), Johnsgard (1988), Meyer de Schauensee (1984), Morioka (1957), Ræthel (1988), Schenck *et al.* (1967), Severinghaus & Blackshaw (1976), Tang Chan-zhu (1990).

87. Hainan Hill-partridge

Arborophila ardens

French: Torquéole de Hainan German: Hainanbuschwachtel Spanish: Arborófila de Hainán

Other common names: White-eared Hill-partridge, Hainan Tree-partridge/Partridge

Taxonomy. *Arboricola ardens* Styan, 1892, Liuowowan, Hainan Island.

Monotypic.

Distribution. Mountains of Hainan, S China. May occur in S Guangxi.

Descriptive notes. c. 28 cm; one male 300 g, one female 237 g. Distinctive bright reddish orange necklace contrasts vividly with mostly black head offset by white spot on ear-coverts. Female similar to male, but paler below. Immature apparently similar to adult, but lacks reddish necklace.

Habitat. Inhabits evergreen tropical forests and woods between 750 m and 1200 m.

Food and Feeding. No information available, other than that tree seeds and snails have been recorded in diet.

Breeding. No information available.

Movements. No information available.

Status and Conservation. ENDANGERED. Mace-Lande: Endangered. Considered to be threatened because very little suitable habitat remains, with forest cover on Hainan reduced from c. 8630 km² to 2420 km²; population probably numbers much less than 10,000 individuals: known from five localities, including Ba Wang Ling and Wuzhishan Nature Reserves. Restricted range; occurs in Hainan Endemic Bird Area. Apparently common in Ba Wang Ling Nature Reserve, although the level of protection that this affords is uncertain. Threats are those to habitat, especially extraction of trees, conversion to agricultural land and general degradation; species is also hunted.

Bibliography. Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Collar & Andica (1988), Davison (1982a), Etchécopar & Hue (1978), Johnsgard (1988), Meyer de Schauensee (1984), Morioka (1957), Ræthel (1988).

88. Chestnut-bellied Hill-partridge

Arborophila javanica

French: Torquéole de Java

German: Javabuschwachtel

Spanish: Arborófila de Java

On following pages: 89. Grey-breasted Hill-partridge (*Arborophila orientalis*); 90. Brown-breasted Hill-partridge (*Arborophila brunneopectoris*); 91. Orange-necked Hill-partridge (*Arborophila davidi*); 92. Chestnut-headed Hill-partridge (*Arborophila cambodiana*); 93. Bornean Hill-partridge (*Arborophila hyperythra*); 94. Red-billed Hill-partridge (*Arborophila rubrirostris*).

Other common names: Javan Hill-partridge, Chestnut-bellied Partridge

Taxonomy. *Tetrao javanicus* Gmelin, 1789, Java.

Some authors include present species in a superspecies with *A. orientalis* and *A. brunneopectus*, and all three are sometimes considered conspecific; others attribute morphological similarities to convergent evolution; sometimes *A. rufipectus* or *A. hyperythra*, or both, also included in the superspecies. Three subspecies recognized.

Subspecies and Distribution.

- A. f. javanica* (Gmelin, 1789) - mountains of W Java.
A. f. bartelsi Siebers, 1929 - mountains of WC Java.
A. f. lavuana Bartels, 1938 - mountains of EC Java.

Descriptive notes. c. 28 cm; 257-286 g. One of most distinctive *Arborophila*, quite dissimilar to any of congeners. Female as male. Immature has white throat, dark brown breast and some white spots on scapulars. Races vary essentially in head pattern.

Habitat. Forest between 300 m and 3000 m.

Food and Feeding. No information available.

Breeding. Season apparently extended, with records from Jan-Apr and Jul-Nov. Lays up to 4 eggs. No further information available.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. Little direct

information; species considered threatened due to habitat loss, and forest clearance has probably led to extinction from lower elevations. Restricted range; occurs in Javanese and Balinese Mountains Endemic Bird Area. Species occurs in several protected areas of various categories, some of which are very small. Still common on Gunung Gede-Pangrango and on Gunung Halimun. Main problems are loss, degradation and resultant fragmentation of habitat; some trapping for bird trade poses additional threat. Not protected by Indonesian law.

Bibliography. Andrew (1985, 1992), van Balen (1992), Davison (1982a), Hellebrekers & Hoogerwerf (1967), Holmes (1989), Johnsgard (1988), MacKinnon (1988), MacKinnon & Phillips (1993), Raethel (1988), Schönwetter (1967), Wells (1985).

89. Grey-breasted Hill-partridge

Arborophila orientalis

French: Torquéole de Sumatra

Spanish: Arborófila de Sumatra

German: Sumatrabuschwachtel

Other common names: Bare-throated Hill-partridge, Grey-breasted Partridge; Campbell's Hill-partridge (*campbelli*)

Taxonomy. *Perdix orientalis* Horsfield, 1821, Blambangan, east Java.

Some authors include present species in a superspecies with *A. javanica* and *A. brunneopectus*, and all three are sometimes considered conspecific; others attribute morphological similarities to convergent evolution; sometimes *A. rufipectus* or *A. hyperythra*, or both, also included in the superspecies. Race *campbelli* sometimes considered to constitute separate species. Four subspecies normally recognized.

Subspecies and Distribution.

- A. o. campbelli* (Robinson, 1904) - mountains of Peninsular Malaysia.
A. o. rolli (Rothschild, 1909) - Batak Highlands, N Sumatra.
A. o. sumatrana Ogilvie-Grant, 1891 - mountains of C Sumatra.
A. o. orientalis (Horsfield, 1821) - mountains of E Java.

Descriptive notes. c. 28 cm; c. 268 g. Head shows distinctive patterns in black and white, varying with race. Female has duller black on head. Immature has pale shaft streaks, is usually more rufous below, and has some barring on breast. Racial variation considerable, mainly in head pattern and underpart coloration, and also in presence or absence of bold markings on underparts.

Habitat. Primary forest, mainly upper dipterocarp, lower montane and tall upper montane forest, between 500 m and 2200 m; altitude limits vary according to locality.

Food and Feeding. Diet includes palms, *Pra-*

tia berries and invertebrates, especially termites and snails.

Breeding. One clutch of 2 eggs found in Mar, at base of palms in Selangor, Malaysia; another nest with 4 eggs also reported. No further information available.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Lande: *orientalis* vulnerable; *campbelli* vulnerable. Only recent information available on *orientalis* comprises reports from 3 sites, Meru Betiri National Park, and Yang Highlands and Ijen Crater Nature Reserves; only a small part of the first two includes suitable habitat. Other races are respectively believed to be sparsely distributed in suitable habitat in Malaysia, and common in Sumatra; both zones may hold the species at undocumented sites in mountains where habitat is not threatened. Population thought to be declining slightly. Not protected by Indonesian law. Directly exploited for food and for bird trade in some areas. CITES III in Malaysia.

Bibliography. van Balen (1992), Davison (1982a), Davison & Scriven (1987), Gibson-Hill (1949, 1952), Holmes (1989), Johnsgard (1988), MacKinnon (1988), MacKinnon & Phillips (1993), van Marle & Voois (1988), Medway & Wells (1976), Robinson & Chasen (1936), Robinson & Kloss (1921, 1924), Wells (1985).

90. Brown-breasted Hill-partridge

Arborophila brunneopectus

French: Torquéole à poitrine brune

German: Braunbrust-Buschwachtel

Spanish: Arborófila Pechiparda

Other common names: Bar-backed/Barred Hill-partridge, Brown-breasted Partridge

Taxonomy. *Arboricola brunneopectus* Blyth, 1855, Muleyit, Tenassarim.

Some authors include present species in a superspecies with *A. javanica* and *A. orientalis*, and all three are sometimes considered conspecific; others attribute morphological similarities to convergent evolution; sometimes *A. rufipectus* or *A. hyperythra*, or both, also included in the superspecies. Birds of Guangxi (CS China) probably belong to race *henrici*, but sometimes ascribed to nominate race. Three subspecies recognized.

Subspecies and Distribution.

A. b. brunneopectus (Blyth, 1855) - CS China (SW Yunnan) through E Burma and N Laos to W Thailand.

A. b. henrici (Oustalet, 1896) - N & C Vietnam; probably also CS China (Guangxi).

A. b. albigula (Robinson & Kloss, 1919) - SC Vietnam.

Possible occurrence and distribution in C & S Laos uncertain; also race, or races, involved.

Descriptive notes. c. 28 cm; male c. 317 g, female c. 268 g. Barring on back, greyish brown or brown breast, and black and white spots on flanks are distinctive in combination. Female similar to male. Immature has pink to orange legs. Races separated mainly on coloration of head and neck, and also on flank markings.

Habitat. Evergreen forests up to 1350 m, or even as high as 1800 m, depending on locality.

Food and Feeding. No information available.

Breeding. Only nest record is from early Jun, near Rangoon, Burma: 4 eggs in a scrape well filled with bamboo leaves and grass, in open

bamboo. No further information available.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Lande: *brunneopectus* safe; *albigula*/*henrici* vulnerable. Nominate *brunneopectus* considered widespread in 1940's, but currently considered vulnerable in Thailand, and rare in SW Yunnan (China), so may be in need of attention. Races *albigula* and *henrici* occupy restricted range in both Vietnam, where little habitat remains, and China. Recently *albigula* recorded at six sites on Da Lat and Di Linh Plateaux, and *henrici* from Bach Ma National Park, all in Vietnam; *albigula* not reported from any protected area. Continuous reduction and fragmentation of habitat is major problem; species is also hunted for food.

Bibliography. Baker (1928), Cheng Tso-hin (1987), Davison (1982a), Deignan (1945), Delacour & Jabouille (1931), Eames *et al.* (1992), Etchécopar & Hüe (1978), Johnsgard (1988), Lekagul & Round (1991), Meyer de Schauensee (1984), Robson *et al.* (1989, 1993a, 1993b), Schönwetter (1967), Smythies (1986), Tang Chan-zhu (1990), Williamson (1918).

91. Orange-necked Hill-partridge

Arborophila davidi

French: Torquéole de David

German: Davidbuschwachtel

Spanish: Arborófila de David

Other common names: Orange-breasted/David's Hill-partridge, Orange-necked Partridge

Taxonomy. *Arborophila davidi* Delacour, 1927, at c. 250 m. Phurieng, 60 km east of Saigon (Ho Chi Minh), Cochinchina.

Monotypic.

Distribution. S Vietnam.

Descriptive notes. c. 28 cm; c. 241 g. Pattern of head and neck, together with bold black and white barring on flanks, present rather distinctive combination. Female and immature undescribed.

Habitat. Only known from areas of dense vegetation, including wooded country in rolling hills, and non-thorny bamboo forest up to 10 m tall. Occurs between 200 m and 250 m.

Food and Feeding. No information available.

Breeding. No information available.

Movements. No information available.

Status and Conservation. INDETERMINATE. Mace-Lande: Endangered. Only known

from type specimens collected in 1927, until recently when seen twice in 3 days in Nam Bai Cat Tien National Park. Failure to find species at other sites and limited extent of habitat available may indicate a population in the hundreds. Restricted range; occurs in Cochinchina Endemic Bird Area. Lack of information makes it difficult to assess threats, but degradation and loss of lowland habitats are likely to have affected the species adversely.

Bibliography. Collar & Andrew (1988), Davison (1982a), Delacour (1927), Delacour & Jabouille (1931), Delacour *et al.* (1927), Eames *et al.* (1992), Johnsgard (1988), Raethel (1988), Robson *et al.* (1993b), Wildash (1968).

92. Chestnut-headed Hill-partridge

Arborophila cambodiana

French: Torquéole du Cambodge

Spanish: Arborófila de Camboya

German: Kambodscha-Buschwachtel

Other common names: Rufous-faced Hill-partridge, Chestnut-headed Partridge

Taxonomy. *Arborophila cambodiana* Delacour & Jabouille, 1928, 1000 m, Bokor, Kampuchea. Race *diversa* might merit treatment as separate species. Two subspecies recognized.

Subspecies and Distribution.

A. c. diversa Riley, 1930 - SE Thailand.

A. c. cambodiana Delacour & Jabouille, 1928 - SW Kampuchea.

Descriptive notes. c. 29 cm; male c. 318 g, female c. 257 g. Mantle and upper back broadly barred black is best distinction from *A. hyperythra*. Female similar to male, but smaller; pattern more variable in female, which sometimes has heavier barring above. Immature probably less spotted below. Race *diversa* has duller face with more marked eyeline, and black and white scaling extending onto belly.

Habitat. Occurs in tropical evergreen forest on mountains, above 700 m.

Food and Feeding. No information available.

Breeding. No information available.

Movements. No information available.

Status and Conservation. RARE. Mace-Lande: *cambodiana* vulnerable; *diversa* endangered. Nominate *cambodiana* is very poorly known; endemic to Cardammon and Elephant Mts from where there is no recent ornithological information; assumed to be declining as consequence of habitat loss. Race *diversa* known only from Namtok Phliu National Park and Khao Soi Dao Wildlife Sanctuary; numbers probably in low hundreds and still declining. Main threats throughout range are likely to be habitat destruction and over-exploitation for food.

Bibliography. Collar & Andrew (1988), Davison (1982a), Delacour & Jabouille (1931), Johnsgard (1988), King *et al.* (1975), Lekagul & Cronin (1974), Lekagul & Round (1991), Raethel (1988), Riley (1938), Round (1988).

93. Bornean Hill-partridge

Arborophila hyperythra

French: Torquéole de Bornéo

German: Borneobuschwachtel

Spanish: Arborófila de Borneo

Other common names: Bornean Partridge/Tree-partridge; Red-breasted Hill-partridge (*hyperythra*); Kinabalu Hill-partridge (*erythrophrys*)

Taxonomy. *Bambusicola hyperythra* Sharpe, 1879, Lawas River, Borneo.

Sometimes included in proposed superspecies formed by *A. javanica*, *A. orientalis* and *A. brunneopectus*. Race *erythrophrys* has been considered to merit treatment as separate species. Two subspecies recognized.

Subspecies and Distribution.

A. h. hyperythra (Sharpe, 1879) - mountains of NC Borneo.

A. h. erythrophrys (Sharpe, 1890) - Mt Kinabalu, Sabah (NE Borneo).

Descriptive notes. c. 25 cm; c 270 g. Rich reddish face and breast distinctive, as is pattern on flanks, mainly black with white spotting. Best separated from rather similar *A. cambodiana* by generally paler, more faintly marked upperparts, and more prominent dark eyeline. Female similar to male, but has smaller, browner spots on flanks. Immature undescribed. Race *erythrophrys* has more elaborate pattern on head; birds from Sarawak variable, sometimes showing extensive grey on supercilium and even down onto cheeks, as well as a darker breast.

Habitat. Montane forest of various types in Kalimantan, including primary lower montane forest between c. 1200 m and 1800 m; also found down to c. 600 m. Apparently associated with bamboo and thickets in forest.

Food and Feeding. Diet includes acorns and variety of other seeds, fruits, grubs, termites, beetles, crickets and ants.

Breeding. Nest is domed, with a hole at the side c. 2-3 cm above the ground. No further information available.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. Few recent records, such as that from Ulu Barito in Kalimantan, a southward range extension; also known from Gunung Mulu National Park in Sarawak, and Kinabalu National Park in Sabah. Likely, however, to occur throughout suitable habitat in mountains of Borneo; reported to be common in Kelabit Highlands of NE Kalimantan and neighbouring Sarawak. Restricted range; occurs in Borneo Mountains Endemic Bird Area. Habitat is being lost and degraded as result of logging; possibly overhunted for food and sport in Kalimantan.

Bibliography. Andrew (1992), van Balen (1992), Davison (1980c, 1982), Dutson (1990), Holmes (1989), Johnsgard (1988), MacKinnon & Philipps (1993), Raethel (1988), Smythies (1957, 1981), Wells (1985), Wilkinson *et al.* (1991a, 1991b).

94. Red-billed Hill-partridge

Arborophila rubrirostris

French: Torquéole à bec rouge

German: Rotschnabel-Buschwachtel

Spanish: Arborófila Piquirroja

Other common names: Red-billed Tree-partridge/Partridge

Taxonomy. *Pelopendix rubrirostris* Salvadori, 1879, Mount Singgalang, Sumatra. Monotypic.

Distribution. Mountains of Sumatra.

Descriptive notes. c. 28 cm; male c. 243 g, female c. 209 g. Very distinctive flank pattern, all black with thin white bars; red bill and eye-ring also characteristic. Amount of white on head very variable, especially on throat, with N populations normally showing more white than those of S; incipient white supercilium. Female like male, but on average has more white on lores and chin.

Habitat. Montane forest, and even scrub in pine forest; occurs between 900 m and 2500 m; possibly prefers steep gullies.

Food and Feeding. No information available.

Breeding. No information available.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. Only known from three areas in Sumatra, but suitable habitat is still apparently widespread in mountains of Sumatra. Montane habitat is relatively secure at present and numbers may be stable. Restricted range; occurs in Sumatra and Peninsular Malaysia Endemic Bird Area. Threats to habitat represent a problem only in some areas. Not protected by Indonesian law.

Bibliography. Andrew (1992), van Balen (1992), Davison (1982a), Holmes (1989), Johnsgard (1988), van Marle & Voous (1988), Meyer de Schauensee & Ripley (1940), Raethel (1988), Robinson & Kloss (1918, 1924), Wells (1985).

95. Green-legged Hill-partridge

Arborophila chloropus

French: Torquéole des bois **German:** Grünfuß-Buschwachtel **Spanish:** Arborófila Pativerde
Other common names: Scaly-breasted/Woodland Hill-partridge, Green-legged Tree-partridge/Partridge

Taxonomy. *Tropicoperdix chloropus* Blyth, 1859, mountains of Tenasserim, Burma = Muleyit. Sometimes placed in genus *Tropicoperdix*. Probably forms superspecies with *A. merlini* and *A. charltonii*, but taxonomy of these three forms poorly understood and requires revision; present species has been considered a race of *A. charltonii*; race *tonkinensis* appears to be intermediate, and may actually belong with *A. charltonii*. Five subspecies currently recognized.

Subspecies and Distribution.

A. c. chloropus (Blyth, 1859) - SC China (S Yunnan) S to Burma (S to N Tenasserim) and W Thailand.

A. c. peninsularis Meyer de Schauensee, 1941 - SW Thailand.

A. c. tonkinensis (Delacour, 1927) - N Vietnam.

A. c. olivacea (Delacour & Jabouille, 1928) - Laos and Kampuchea.

A. c. cognacqi (Delacour & Jabouille, 1924) - S Vietnam.

Descriptive notes. c. 30 cm; 250-300 g. Green legs distinctive. Differs from very similar *A. merlini* in having brighter rufous area on breast, less distinct markings on flanks and lower breast, and green legs; lacks thin black line at base of neck and reddish ear-coverts of *A. charltonii*. Female as male. No information available on immature plumage. Races separated mainly on breast colouring; race *tonkinensis* (possibly pertaining to *A. charltonii*) is intermediate in plumage between present species and *A. charltonii*.

Habitat. Inhabits dense primary forest, but apparently also sometimes found in secondary

forest up to 1400 m; occurs in both evergreen and mixed deciduous forest, as well as patches of bamboo.

Food and Feeding. Seeds, berries and termites reported in diet.

Breeding. Single record of 3 eggs found in May, apparently of race *olivacea*. No further information available.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Little detailed information available. Believed to number in low hundreds of thousands in Thailand, where still said to be common; rare in Yunnan (China); only scattered records from N Burma from 1940's; race *tonkinensis* locally quite common and known from at least three protected areas, but possibly threatened. In Thailand, populations considered more or less stable in protected areas, but declining elsewhere through deforestation and overhunting.

Bibliography. Cheng Tso-hin *et al.* (1978), Davison (1982a), Deignan (1945), Delacour & Jabouille (1931), Gibson-Hill (1952), Johnsgard (1988), Lekagul & Round (1991), Meyer de Schauensee (1984), Ruetzel (1988), Riley (1938), Robinson & Kloss (1921, 1924), Robson *et al.* (1989, 1993a, 1993b), Smythies (1985).

96. Annam Hill-partridge

Arborophila merlini

French: Torquéole de Merlin **German:** Gelbfuß-Buschwachtel **Spanish:** Arborófila de Annam
Other common names: Annamese Hill-partridge, Annam Tree-partridge/Partridge

Taxonomy. *Tropicoperdix merlini* Delacour & Jabouille, 1924, Mailanh, Quangtr, Vietnam. Sometimes placed in genus *Tropicoperdix*. Probably forms superspecies with *A. chloropus* and *A. charltonii*, but taxonomy of these three forms poorly understood and requires revision; present species has been considered a race of *A. charltonii*. Two subspecies currently recognized.

Subspecies and Distribution.

A. m. merlini (Delacour & Jabouille, 1924) - interior of C Vietnam.

A. m. vivida (Delacour, 1926) - coastal hills of C Vietnam.

Descriptive notes. c. 30 cm. Very similar to *A. chloropus*, from which differs most conspicuously in yellowish legs and in much more distinct black scaling on flanks and lower breast. Female apparently as male. No information available on immature plumage. Race *vivida* differs only slightly from nominate.

Habitat. A lowland forest specialist, occurring below 600 m.

Food and Feeding. No information available.

Breeding. No information available.

Movements. No information available.

Status and Conservation. ENDANGERED.

Mace-Lande: Endangered. Very little information

available on status and trend; species possibly declining as result of habitat loss and degradation. Known from Bach Ma National Park, where thought to be common in 1990. Restricted range; occurs in Annamese Lowlands Endemic Bird Area.

Bibliography. Davison (1982a), Delacour & Jabouille (1931), Johnsgard (1988), Robson *et al.* (1993a, 1993b).

97. Chestnut-necklaced Hill-partridge

Arborophila charltonii

French: Torquéole à poitrine châtain **Spanish:** Arborófila Pechicastaña
German: Charltonbuschwachtel

Other common names: Chestnut-breasted Hill-partridge(!), Chestnut-necklaced Tree-partridge/Partridge

Taxonomy. *Perdix charltonii* Eyton, 1845, Malacca.

Sometimes placed in genus *Tropicoperdix*. Probably forms superspecies with *A. chloropus* and *A. merlini*, both of which have been considered races of present species; taxonomy of these three forms poorly understood and requires revision; *A. chloropus tonkinensis* appears to be intermediate, and may actually belong with present species; validity of race *atjenensis* has been questioned. Three subspecies currently recognized.

Subspecies and Distribution.

A. c. charltonii (Eyton, 1845) - S Thailand and S Burma to Peninsular Malaysia.

A. c. atjenensis Meyer de Schauensee & Ripley, 1940 - Aceh, N Sumatra; old records from S Sumatra.

A. c. graydoni (Sharpe & Chubb, 1906) - Sabah, NE Borneo.

Descriptive notes. 28-30 cm. Differs from apparently closely related *A. chloropus* and *A. merlini* by generally brighter plumage, especially chestnut band on upper breast, and tawny belly; reddish patch on ear-coverts; yellow legs. Female similar to male. Immature duller with more dark barring on upperparts. Races differ mainly in face and wing patterns, and in intensity of chestnut on breast band.

Habitat. Inhabits primary lowland forest up to about 300 m; also found at times in heavily disturbed forest.

Food and Feeding. Seeds, berries and termites reported in diet.

Breeding. No reliable information available.

Movements. No information available.

Status and Conservation. RARE. Mace-Lande: *charltonii* endangered; *graydoni* endangered; *atjenensis* critical. Nominote *charltonii* possibly numbers fewer than 1000 individuals, an estimate based on extent of lowland forest remaining; reported from quite disturbed sites in S Thailand, where may be on verge of extinction. Race *graydoni* may number in low hundreds, with decline as result of habitat destruction on massive scale; reported to be moderately common in logged forest in Sabah; recorded recently only from Danum Valley, but may occur elsewhere. Race *atjenensis* known only from extreme N Sumatra, and probably also from S Sumatra; not reported from any protected area, but may occur in NE Gunung Leuser National Park; some of formerly suitable habitat in S Sumatra has been completely deforested; no recent records from anywhere in Sumatra, and may survive only in N; large-scale habitat destruction implies population in low hundreds. Extensive habitat loss threatens all 3 races, and surveys are urgently required to establish where species survives, and extent of suitable habitat that remains. Not protected by Indonesian law. CITES III in Malaysia.

Bibliography. van Balen (1992), Chasen (1939), Collar & Andrew (1988), Davison (1982a), Davison & Scriven (1987), Gibson-Hill (1949), Holmes (1989), Johns (1986, 1989), Johnsgard (1988), Lekagul & Round (1991), MacKinnon & Philipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Robinson (1913, 1915a, 1915b), Robinson & Kloss (1921), Schönewetter (1967), Smythies (1957, 1981, 1986), Wells (1985).

Genus CALOPERDIX Blyth, 1861

98. Ferruginous Wood-partridge

Caloperdix oculea

French: Rouloul ocellé **German:** Augenwachtel **Spanish:** Perdicilla Herrumbrosa
Other common names: Ferruginous Partridge

Taxonomy. *Perdix oculea* Temminck, 1815, India.

Sumatran birds have traditionally been placed in race *sumatrana*, but name *ocellata* has priority. Three subspecies recognized.

Subspecies and Distribution.

C. o. oculea (Temminck, 1815) - SE Burma and SW Thailand to Peninsular Malaysia.

C. o. ocellata (Raffles, 1822) - Sumatra.

C. o. borneensis Ogilvie-Grant, 1892 - NC and extreme NE Borneo.

Descriptive notes. 23-27 cm; one male 190 g. Very distinctive combination of bright rufous head and underparts, black and white scaling on upper back, mantle, sides of breast and flanks, and bold patterning on rest of upperparts. Male occasionally has two spurs; female has one short 'spur only'. Immature has black markings on nape and chest. Races very similar, differing only slightly in markings, e.g. extent of scaling on lower flanks.

Habitat. Found in evergreen forest, in a variety of situations according to locality, including dry forest in mountains, and both primary and secondary forest in sandy valleys - also in secondary scrub, which is main habitat in Sumatra. Occurs from lowlands up to c. 1000 m.

Food and Feeding. Seeds, grasses, berries, fallen figs and insects reported. Forages in groups of a few birds.

Breeding. No reliable report from Malay Peninsula; in Borneo, locals report domed nest with entrance hole and c. 8-10 eggs in Dec-Jan; 2 downy young collected in Padang Highlands, W Sumatra, but no further details. Incubation 18-20 days (in captivity).

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. Widespread in Sumatra, but apparently rare, with fairly few recent records; very scarce in Thailand; no information from Malaysia. Believed declining as consequence of habitat destruction throughout range; overhunted in Thailand. Known from several protected areas in all three countries, including Kaeng Krachan

On following pages: 99. Crimson-headed Partridge (*Haematorix sanguiceps*); 100. Crested Wood-partridge (*Ruficapra ruficapra*); 101. Stone Partridge (*Ptilopus ptilopus*); 102. Mountain Bamboo-partridge (*Bambusiocha fuscata*); 103. Chinese Bamboo-partridge (*Bambusiocha thoracica*); 104. Red Spurtail (*Galloperdix spadicea*); 105. Painted Spurtail (*Galloperdix lunulata*); 106. Ceylon Spurfowl (*Galloperdix bicalcarata*).

National Park in Thailand, Taman Negara National Park in Malaysia and Gunung Leuser National Park on Sumatra. Recent records from 100 m at Sako, W Sumatra, at c. 800 m in W Sumatra, in dry forest in the lowlands of Way Kambas, SE Sumatra, and one at 1000 m at Gunung Leuser National Park. Not protected by Indonesian law. CITES III in Malaysia.

Bibliography. van Balen (1992), Chasen (1939), Davison (1982a), Davison & Scriven (1987), Gibson-Hill (1949), Holmes (1989), Johnsgard (1988), Lekagul & Round (1991), MacKinnon & Philipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Robinson (1915a, 1915b), Robinson & Kloss (1918, 1921, 1924), Round (1988), Smythies (1957, 1981, 1986), Wells (1985).

Genus *HAEMATORTYX* Sharpe, 1879

99. Crimson-headed Partridge

Haematortyx sanguineps

French: Rouloul sanglant **German:** Rotkopfwachtel **Spanish:** Perdicilla Cabecirroja
Other common names: Crimson-headed Wood-partridge

Taxonomy. *Haematortyx sanguineps* Sharpe, 1879 Lawas River, Borneo.

Monotypic.

Distribution. Mountains of N Borneo.

Descriptive notes. c. 25 cm; one male 330 g. Crimson head and blackish plumage very distinctive. Female lacks spurs; plumage generally browner black, with throat, neck and breast rufous orange. Immature duller, with less extensive crimson colouring.

Habitat. Inhabits lower montane forest, including poor quality forest in sandy areas; recorded between roughly 1000 m and 1500 m.

Food and Feeding. Berries and insects, and also small crustaceans recorded in diet.

Breeding. Earliest reported laying mid-Jan.

Nests in *kerangas* forest; nest is made of dry leaves, and situated in a tuft of grass or some

similar situation. Lays 8-9 eggs; incubation 18-19 days (figures presumably from captivity).

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. Currently considered near-threatened. Locally common but range much reduced and population therefore assumed to be declining; anecdotal information and restricted range together suggest total of fewer than 10,000 individuals remain. Status unknown in watershed regions of C Kalimantan, where species formerly occurred. Not known from any protected area in Kalimantan, indeed no recent records at all from Kalimantan; reported in Gunung Mulu National Park, Sarawak; occurs in Borneo Mountains Endemic Bird Area. Main causes of assumed population decline are loss and degradation of habitat. Not protected by Indonesian law.

Bibliography. Andrew (1992), van Balen (1992), Davison (1980c), Dutton (1990), Holmes (1989), Johnsgard (1988), MacKinnon & Philipps (1993), Raethel (1988), Smythies (1957, 1981), Wells (1985).

Genus *ROLLULUS* Bonnaterre, 1791

100. Crested Wood-partridge

Rollulus rouloul

French: Rouloul couronné **German:** Straußwachtel **Spanish:** Perdiz Rulul
Other common names: Crested Partridge, Rouloul

Taxonomy. *Phasianus Rouloul* Scopoli, 1786, Malacca.

Often misspelt *rouloul*. Monotypic.

Distribution. S Burma and SW Thailand through Peninsular Malaysia to Sumatra (and some smaller inshore islands) and Borneo.

Descriptive notes. c. 26 cm; male c. 232 g, female c. 202 g. Unmistakable, with spectacular reddish crest, all dark plumage and bright red bare parts. Female very different from male, but equally distinctive, with most of plumage green and head grey. Immature resembles female, but more mottled above; immature male has greyish belly.

Habitat. Evergreen forest, mainly in plains and foothills, but in places up to 1200 m.

Food and Feeding. Seeds, large fruits, large beetles, wood ants, and small molluscs. Association with wild pigs reported, whereby the birds can feed on discarded fragments of fruit

which they would be unable to tackle whole.

Breeding. Laying in most months in Peninsular Malaysia: Dec and Apr in Perak; Feb and Jul in Pahang; Oct in Negri Sembilan; and chicks in Feb-May in Perak, and Sept in Selangor. Nest is simply a depression in dry leaves. Lays 5-6 eggs (occasionally 4); incubation (in captivity) 18-19 days (by Semalokian).

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. Formerly widespread but now scarce in Thailand; not uncommon in extreme S Burma in 1940's. Few recent records from Indonesia, although may still be widespread in lowlands, a severely threatened habitat throughout

the whole region; in Sumatra, common at Ketambe (Gunung Leuser) and at Way Kambas; one record at Tanjung Puting, Kalimantan; possibly endangered or extinct on Bangka I and Belitung I (both off SE Sumatra). Presumed to be declining because of logging in several areas, e.g. Peninsular Malaysia; considered vulnerable because of pace of habitat loss and assumed consequent decline in distribution of what was once a widespread species. Reported from several protected areas in three different countries: Khao Pra Bang Khram and Khlong Nakha in Thailand; Taman Negara and Gunung Mulu National Parks in Malaysia; and Gunung Leuser and Tanjung Puting National Parks, and Way Kambas National Park, in Indonesia. Not protected by Indonesian law. CITES III in Malaysia.

Bibliography. van Balen (1992), Chasen (1939), Coomans de Ruiter (1946), Corder (1992), Davison (1979a, 1980c), Davison & Scriven (1987), Farrand & Olson (1973), Gibson-Hill (1949), Holmes (1989), Holmes & Burton (1987), Humphrey & Bain (1990), Johns (1986, 1989), Johnsgard (1988), Lekagul & Round (1991), MacKinnon & Philipps (1993), Madoc (1976), Mann (1987), van Marle & Voous (1988), McGowan (1992b), Medway & Wells (1976), Ogilvie (1949), Robinson (1915a, 1915b), Robinson & Chasen (1936), Robinson & Kloss (1918, 1921, 1924), Round (1988), Smythies (1957, 1981, 1986), Wells (1985).

Genus *PTILOPACHUS* Swainson, 1837

101. Stone Partridge

Ptilopachus petrosus

French: Poulette de roche **German:** Felsenhenne **Spanish:** Gallinita Roquera

Taxonomy. *Tetrao petrosus* Gmelin, 1789, Gambia.

Proposed races *saturator*, *butleri*, *brehmi*, *emini* and *florentiae* included within nominate *petrosus*. Two subspecies normally recognized.

Subspecies and Distribution.

P. p. petrosus (Gmelin, 1789) - Senegal E to Kenya.

P. p. major Neumann, 1908 - NW Ethiopia.

Descriptive notes. c. 25 cm; male c. 190 g. Presents distinctive aspect due to habit of cocking tail like a bantam fowl; generally appears rather dark. Female has creamy white belly patch. Race *major* is larger and paler, and has broader streaks on flanks.

Habitat. Typically occurs in dense vegetation on boulder strewn rocky hillsides, from 600 m to 1500 m, especially on granite kopjes and laterite outcrops; also lowland savanna, steep dry wooded watercourses, broken woodland with grassland and cultivation nearby, and sandy plains with adequate scrub cover; in Gambia, occurs right down to coastal areas.

Food and Feeding. Grass and herb seeds, green leaves, fruits and buds, and some insects.

Breeding. Season may be influenced by rainfall, with breeding taking place during rains in dry parts of range, and during dry season in wet areas; Dec-Jul in Senegambia; Dec-Mar in Sierra Leone; Nov-Dec in N Mali; Feb-May in S Mali; Jun-Jul in Niger; Jul, Jan, Feb and Apr (young chicks) in Nigeria; all months in Central African Republic; Dec-Jul in Sudan; Aug-Sept in Ethiopia (including Eritrea). Nest is a scrape, well hidden at the base of a rock, tree or tuft of grass and occasionally lined with grass. Lays 4-6 eggs; chicks have blackish chestnut down above, dark brown speckled black below. Young remain with parents for some time, probably until following breeding season.

Movements. Sedentary. Flies only when hard pressed, using a fast, direct style of flight. Climbs cliff faces with some ease.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Little detailed information available, but species considered common, even abundant, in many areas, though rather locally distributed. Subject to some hunting pressure, but there is no indication that this constitutes a major problem.

Bibliography. Ash (1992), Bannerman (1953, 1963), Britton (1980), Brown & Britton (1980), Clarke (1966), Gore (1990), Grimes (1987), Jackson & Selater (1938), Johnsgard (1988), Lewis & Pomeroy (1989), Mackworth-Præd & Grant (1957, 1970), Morel & Morel (1990), Morris (1951), Nikolaus (1987), Raethel (1988), Urban *et al.* (1986).

Genus *BAMBUSICOLA* Gould, 1863

102. Mountain Bamboo-partridge

Bambusicola fytchii

French: Bambusicole de Fytch **Spanish:** Bambuscola Montana
German: Gelbbrauen-Bambushuhn

Taxonomy. *Bambusicola fytchii* Anderson, 1871, Pensee, Yunnan, China.

Two subspecies recognized.

Subspecies and Distribution.

B. f. hopkinsoni Godwin-Austen, 1874 - NE India (Assam and Arunachal Pradesh) S to E Bangladesh and E to N Burma.

B. f. fytchii Anderson, 1871 - SC China (Sichuan and Yunnan) S to EC Burma, NW Thailand and N Vietnam.

Descriptive notes. c. 35 cm; 256-400 g. Distinctive pattern on head and underparts: belly creamy white to pale buff; chestnut outer tail feathers conspicuous in flight. Female usually unspeckled. Immature has wide buffy shaft streaks. Race *hopkinsoni* differs only slightly in details of plumage.

Habitat. Open scrub forest, thickets, and mixed scrub and tall grassland along watercourses at 500-3000 m; also extensively deforested hillsides, where inhabits swaddens with scattered woods above 1000 m.

Food and Feeding. Seeds, berries, shoots and buds, and a variety of invertebrates. Scratches ground.

Breeding. Nesting apparently Mar-Sept (usually Apr-Jul) in China; May-Jul in Burma; Mar-May in India. Nest is a scrape lined with grass and leaves. Usually 4-6 eggs (3-7); incubation 18-19 days, by female only; male stays close to nest.

Movements. Moves out into open to feed in morning and evening, not moving far from water. Flies only when pressed, flying for a few metres before landing in grass.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. Range covers a fairly large area, but distribution believed to be local and fragmented. Considered widespread

and possibly increasing in number in N Thailand; common in Upper Burma; uncommon in China; no recent records from Bangladesh, where may still occur in hill forest in NE & SE of Chittagong Hill Tracts. Formerly found in large numbers in parts of NE India, e.g. up to 27 killed in a single day by 2 hunters; but no recent information. Appears to be undergoing an overall decline. Subject to habitat loss, but is known to affect cultivated areas; hunted in NE Thailand, as well as NE India.

Bibliography. Ali & Ripley (1980), Baker (1935), Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Deignan (1945), Eichécopar & Hùe (1978), Harvey (1990), He Fen-qi *et al.* (1990), Johnsgard (1988), Lekagul & Round (1991), Meyer de Schauensee (1984), Ripley (1982), Sarker (1986), Smythies (1986), Tang Chun-zhu (1990), Yang Xiaojun *et al.* (1991).

103. Chinese Bamboo-partridge

Bambusicola thoracica

French: Bambusicole de Chine

Spanish: Bambuscola China

German: Graubrauen-Bambushuhn

Other common names: Bamboo Partridge

Taxonomy. *Perdix thoracica* Temminck, 1815, India, error = China.

Two subspecies recognized.

Subspecies and Distribution.

B. t. thoracica (Temminck, 1815) - S China, from Sichuan E to Zhejiang and SE through Guizhou to Guangdong.

B. t. sonorivox Gould, 1863 - Taiwan.

Introduced to Japan and Hawaiian Is.

Descriptive notes. c. 31 cm; 200-342 g. Distinctive head pattern. Female usually unspurred. Immature less colourful; has buffy shaft streaks; dark spots on lower back, rump and uppertail-coverts. Race *sonorivox* generally darker, with much smaller rufous throat patch, and blotches on flanks chestnut, not black.

Habitat. Occurs in bamboo forest, shrubs and grassy areas up to 1000 m, or in places to 2000m.

Food and Feeding. Seeds (including nuts), shoots, leaves and invertebrates.

Breeding. No information available on season. Nest at base of tree, under shrub or in grass

cover. Lays 3-7 eggs; incubation 17-18 days, by female only.

Movements. Short seasonal migrations reported, with birds on tops of hills in summer, but lower down in winter.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Believed to be safe from extinction because of fairly large range and the fact that species is considered common in many areas. Population stable in Taiwan, but declining in China, where becoming uncommon in some areas. Threats in China are loss of habitat to agricultural and urban development, as well as over-hunting; pressures on habitat are also known to be affecting species in Taiwan.

Bibliography. Austin & Kuroda (1953), Brazil (1991), Cheng Tso-hin (1987), Cheng Tso-hin *et al.* (1978), Crowe & Crowe (1985), Eichécopar & Hùe (1978), He Fen-qi & Cui Xie-zhen (1990), Johnsgard (1988), King, B.F. (1989a), Lever (1987), Meyer de Schauensee (1984), Severinghaus & Blackshaw (1976), Tang Ze-sheng & Dai Hong-zhen (1960).

Genus GALLOPERDIX Blyth, 1844

104. Red Spurfowl

Galloperdix spadicea

French: Galloperdrix rouge

German: Rotes Spornhuhn

Spanish: Faisanillo Rojo

Taxonomy. *Tetrao spadiceus* Gmelin, 1789, Madagascar, ex Sonnerat, error = Nepal.

Three subspecies recognized.

Subspecies and Distribution.

G. s. caurina Blanford, 1898 - NW India (Aravalli Hills, S Rajasthan).

G. s. spadicea (Gmelin, 1789) - W Nepal and much of Peninsular India (Uttar Pradesh S to Karnataka and Tamil Nadu).

G. s. stewarti Stuart Baker, 1919 - S India (Kerala).

Descriptive notes. 35.5-38 cm; 284-454 g. Upperparts scaled. Female generally has crown somewhat darker, upperparts barred; differs from other female *Galloperdix* by chestnut underparts with black-tipped feathers. Immature male more richly and deeply coloured than similar adult female. Males of different races separated by extent of black on crown, and by shade of chestnut overall, with *stewarti* richer, darker and virtually unscared, and *caurina* paler and glossier; females of different races differ in colour of upperparts.

Habitat. Occupies a variety of habitat types, especially those in hilly ground that afford cover, e.g. deciduous scrub, often close to cultivation, mostly below 1000 m, but up to 2400 m in places.

Food and Feeding. Seeds, berries, fruits, especially figs, and various invertebrates.

Breeding. Reported in most months: *spadicea* generally in Jan-Jun; *caurina* May-Jun; and *stewarti* in most months except the wettest (Jun-Aug). Monogamous. Nest is a scrape. Sometimes lined with a few pieces of grass and some leaves. Usually 2-5 eggs; incubation by female alone, but both parents tend chicks.

Movements. Sedentary. When alarmed, dodges from one piece of cover to another; runs very fast, flying only when hard pressed, and rarely any distance.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Considered safe because of extensive range, throughout which it is considered widely scattered; also because at any rate in some parts, e.g. S India, species occurs in coffee estates and secondary vegetation. No further information available.

Bibliography. Ali (1979), Ali & Ripley (1980), Baker (1935), Crowe & Crowe (1985), Davison (1986d), Inskipp & Inskipp (1985), Johnsgard (1988), Raethel (1988), Ripley (1982), Sankar *et al.* (1993), Uttigari (1993), Zacharias & Gaston (1993).

105. Painted Spurfowl

Galloperdix lunulata

French: Galloperdix lunulée

German: Perlspornhuhn

Spanish: Faisanillo Moteado

Taxonomy. *Perdix lunulata* Valenciennes, 1826, Bengal.

Monotypic.

Distribution. Peninsular India S of Gangetic Plain, except W & NW. Said to occur in W Bangladesh. Old report from Nepal is erroneous

Descriptive notes. c. 32 cm; male 255-285 g, female 226-255 g. Male unmistakable. Female distinguished from other female *Galloperdix* by combination of rufous or chestnut face, yellowish buff throat and ochraceous brown breast. Immature male duller than adult female and more freckled.

Habitat. Thorn scrub and bamboo in dry areas, e.g. boulder strewn hills; usually below 900 m.

Food and Feeding. Seeds, tubers, drupes (*Zizyphus*, *Lantana*, *Ficus*, etc.) and berries reported; also small land molluscs and insects, especially termites.

Breeding. Nesting Jan-Jun, mainly Feb to early May; also in other months at some localities. Nest is a scrape, lined with leaves and grass, under a rock or a root, or on dry bamboo leaves within a clump. Usually 3-4 eggs (sometimes 5); incubation apparently by female alone, but both parents tend young; downy chicks are pale chestnut-rufous above with darker broad central line, earthy brown and chestnut below.

Movements. Presumably sedentary. More reluctant to fly than *G. spadicea*; when alarmed dodges between pieces of cover; runs very fast, flying only when hard pressed and rarely any distance. Hops from rock to rock on stony hill-sides; if flushed, will fly downwards.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Considered safe because of extensive distribution, and because inhabits secondary vegetation in some areas. Occurs in several protected areas (e.g. Indira Gandhi Wildlife Sanctuary, Amaravathy), but clearly does not rely on these for survival. No further information available.

Bibliography. Ali (1979), Ali & Ripley (1980), Baker (1935), Davison (1986d), Johnsgard (1988), Raethel (1988), Ripley (1982), Sankar *et al.* (1993).

106. Ceylon Spurfowl

Galloperdix bicalcarata

French: Galloperdix de Ceylan

German: Ceylonspornhuhn

Spanish: Faisanillo de Ceilán

Taxonomy. *Perdix bicalcarata* J. R. Forster, 1781, Sri Lanka.

Monotypic.

Distribution. Sri Lanka.

Descriptive notes. 33-35.5 cm; male 312-368 g, female 200-312 g. Male unmistakable. Female differs from other *Galloperdix* by combination of rich chestnut ground colour, grey-brown head and white throat. Immature similar to adults, but immature male has fewer, larger white markings than adult.

Habitat. Forested areas in moist situations up to 1500 m.

Food and Feeding. Seeds and berries, termites and other insects; particularly favours *Striatanthus* seeds during flowering years.

Breeding. Season during NE monsoon in Nov-Mar, but breeding also reported in Jul-Sept.

Monogamous. Nest is a scrape lined with leaves and grass, under rock or bush. Usually 2 eggs, but up to 5; chicks have dark brown down.

Movements. Sedentary. When alarmed, dodges between pieces of cover; runs very fast, flying only when hard pressed and rarely any distance.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. No recent detailed information on status, but must be declining because forests are disappearing. Difficult to observe; recently found in reasonable numbers in remnant forest near Kudawa in Sinharaja Forest Reserve. Restricted range; occurs in Sri Lanka Endemic Bird Area. Further survey work required.

Bibliography. Ali & Ripley (1980), Baker (1935), Garner (1993), Henricsson & Jönvall (1988), Phillips (1975), Raethel (1988).

Subfamily PHASIANINAE

Genus *ITHAGINIS* Wagler, 1832

107. Blood Pheasant

Ithaginis cruentus

French: Ithagine ensanglantée

German: Blutfasan

Spanish: Faisán Ensangrentado

Taxonomy. *Phasianus cruentus* Hardwicke, 1821, Nepal. Considerable intergradation between most of the described races suggests that much of the variation observed is probably clinal, and therefore the validity of many races is dubious; race *affinis* doubtfully distinct from nominate *cruentus*, as is *holoptilus* from *rocki*, and *anna* from *berezowskii*. Fourteen subspecies usually recognized.

Subspecies and Distribution.

- I. c. cruentus* (Hardwicke, 1821) - Nepal.
- I. c. affinis* Beebe, 1912 - NE India (Sikkim).
- I. c. tibetanus* Stuart Baker, 1914 - E Bhutan and SE Tibet.
- I. c. kuseri* Beebe, 1912 - NE India (Upper Assam) and SE Tibet.
- I. c. geoffroyi* J. Verreaux, 1867 - SE Tibet.
- I. c. marionae* Mayr, 1941 - border between Burma and China, in region of Yunnan.
- I. c. rocki* Riley, 1925 - CS China (Mekong Valley, NW Yunnan).
- I. c. holoptilus* Greenway, 1933 - CS China (only known from Lichiang District in Yunnan).
- I. c. clarkei* Rothschild, 1920 - CS China (Lichiang Range, NW Yunnan).
- I. c. michaelis* Bianchi, 1903 - NC China (NW Gansu).
- I. c. beicki* Mayr & Birkhead, 1937 - NC China (N Gansu).
- I. c. berezowskii* Bianchi, 1908 - C China (S Gansu and N Sichuan).
- I. c. annae* Mayr & Birkhead, 1937 - WC China (NW Sichuan).
- I. c. sinensis* David, 1873 - C China (Tsinling Mts, Shaanxi).

Descriptive notes. Male 44-48 cm (tail 16.5-18 cm); female 39.5-42 cm (tail 14-15.5 cm); 410-655 g. Rather small partridge-like pheasant. Female much duller, mainly brown, with forehead, face and throat rufescent cinnamon, sometimes tinged with crimson; some females have small spurs. Immature much duller than adult; at 3 weeks old, male clearly greyer than female. Considerable variation between races in extent of red and black on head of males, and in coloration of underparts; also in greater upperwing-coverts, which are green towards SW and reddish towards NE.

Habitat. In Nepal, inhabits high altitude rhododendron scrub and other types of subalpine scrub at 3200-4400 m; in India, found at 2750-4500 m, e.g. in subalpine scrub. Also occurs in pine and juniper forests, and in bamboo. No recent information from Burma but formerly found above 2500 m.

Food and Feeding. In Nepal, feeds principally on moss, leaf litter and grass shoots; droppings in spring included beetle wing cases; other insects also taken. In autumn, apparently feeds on small fruits, leaves, seeds, moss spore cases, bamboo shoots, berries and rose hips; in winter, diet believed to be primarily fir and juniper shoots, berries, moss and bamboo leaves. After heavy snow, species seen feeding on lily seed cases and associated insects. Feeds by scratching; birds seen feeding at all times of day; will feed arboreally on moss-covered branches.

Breeding. Lays from mid-Apr to late June; most nests found in May. Believed to be monogamous, but polygamy and polyandry reported. Nest is a depression in ground, lined with dead grass stems; 4 nests at 3600 m, and 1 at 4000 m. Lays 2-7 eggs; incubation 26-29 days (in captivity); chicks have dull rufous down on upperparts with dark brown marks, paler rufous below.

Movements. Extent of altitudinal movement due to snowfall varies with geographical location. In summer occurs around tree-line and on alpine meadows above, descending in autumn to open coniferous forests of fir and juniper at lower end of altitude range.

Status and Conservation. Not globally threatened. Mace-Land: *cruentus/affinis/tibetanus/geoffroyi/berezowskii/beicki/michaelis/sinensis/anna* s.a.f.e.; *kuseri/rocki/marionae/holoptilus/clarkei* vulnerable. CITES II. A widely distributed species with a range of over 500,000 km²; the area of available habitat within this, however, is much less, as habitat is naturally fragmented being in upper hills and is likely to have been reduced by a variety of activities. Subspecies cluster of *kuseri*, *rocki*, *marionae*, *holoptilus* and *clarkei* may be vulnerable, as these races have combined range of less than 50,000 km², with possibly as little as 25,000 km² of available habitat; probably declining everywhere except in Bhutan. Race *marionae* from Upper Burma was very common around Chimli Pass, but was snared by the Yawjins in 1940's; no information since then. Species as a whole is known from over 70 locations in Tibet, Sichuan, Yunnan, Qinghai, Gansu and Shaanxi, including Wanlang, Taibaishan, Qilianshan and Feping Natural Reserves; in Nepal from over 20 sites including Langtang, Sagarmatha, Rara Lake and Makalu Borun National Parks, and the Annapurna Conservation Area; in India from at least 3 sites, in addition to Sikkim, where it is the state bird, and is reported to be common and widespread. Considered common in Bhutan in mid-1930's, and there is no reason to consider its status any different at present. Threatened by a variety of habitat pressures, including timber extraction, overgrazing of understorey, and conversion of land to agriculture; also hunted.

Bibliography. (1990), Inskipp & Inskipp (1985, 1986, 1993a, 1993b), Kaul & Ahlud (1993), King & Peng Jiao (1991), Lamba (1980), Ledlie & Yonzon (1986a, 1986b), Li Chun-qiu & Li De-hao (1981), Li Gui-yuan & Zhang Qing-mao (1987), Ludlow & Kincaid (1944), Meyer de Schauensee (1985), Robson (1985), Roles (1990), Shi Deng-cou (1985), Smith (1991), Smythes (1986), Tang Chan-zhi (1990), Tysara (1993), Vaurie (1965d), Yang Lan & Li Zhi-xiang (1984), Yao Jian-chu (1989), Yonzon (1987), Yonzon & Chelici (1980), Zheng Guang-mei & Zhang Zheng-wang (1993), Zheng He-xun & Chen Fuguan (1988).

Genus *TRAGOPAN* Cuvier, 1829

108. Western Tragopan

Tragopan melanocephalus

French: Tragopan de Hastings German: Schwarzkopftragopan Spanish: Tragopán Dorsigrís
Other common names: Black-headed/Western Horned Tragopan

Taxonomy. *Phasianus Melanocephalus* J. E. Gray, 1829, Almora, India.

Type locality is outside recorded range of species, but close to its eastern limit; it has been suggested that type specimen was found in a bazaar. Monotypic.

Distribution. NW Himalayas, from N Pakistan to NW India, E to Garhwal, possibly Kumaon and adjacent SW Tibet.

Descriptive notes. Male 68.5-73 cm (tail 22-25 cm), 1800-2150 g; female c. 60 cm (tail 19-20 cm), 1250-1400 g. Male is darkest *Tragopan*; red restricted mainly to neck and upper breast. Female greyish brown with black ocellus-like patches above, and small round white spots below. First-year male similar to adult female in colour, but markings more like those of adult male.

Habitat. Apparently found only in climax, transitional moist or dry temperate forest, typically of brown oak (*Quercus semecarpifolia*) and conifers, with heavy understorey, between c. 2000 m in winter and 3600 m in summer.

Food and Feeding. Few detailed observations, but species believed to be primarily vegetarian, mainly eating new leaves, including those of box, oak and ringal bamboo. Other food items include roots, flowers, and some insects and grubs.

Breeding. Little information. Calling heard at dawn in Mar-Jun. One nest of 6 eggs found in a tree hollow 3 m above ground in late May; another 13 m above ground, possibly an old corvid nest; two other nests on ground; altitude not known. Lays 3-6 eggs; chicks have dark rufous down above, pale buff below, like those of *T. satyra*, but greyer.

Movements. Extent of seasonal altitudinal movements uncertain. In Himachal Pradesh, NW India, believed to be fairly sedentary; elsewhere claimed to breed above 2400 m, up to tree-line, and to winter around 1350 m among oak, chestnut and morena pine.

Status and Conservation. ENDANGERED. Mace-Land: Vulnerable. CITES I. Conservation problems facing present species are better known than for most other species in this family. Total population may number only c. 5000 individuals, and declining. Suitable habitat lost and fragmented by disturbance and removal of understorey through livestock grazing and fodder and firewood collection; also by tree-felling and subsequent agricultural use of land. Collection of non-timber products, e.g. plants for medicinal use, may have a major effect on species during breeding season. Found in several protected areas, including two national parks, the Great Himalayan National Park in NW India, and Machiara National Park in NE Pakistan. Has been subject of several surveys since early 1980's, and was initial focus for the Himalayan Jungle Project in Palas Valley, North-West Frontier Province, Pakistan, where largest population of species occurs; this is a co-operative project involving BirdLife International/WWF/WPA and the Government of Pakistan, amongst others; it seeks to promote local participation in conservation of an extensive tract of mid-altitude temperate forest by developing sustainable use in preference to habitat disruption through logging.

Bibliography. Ali & Ripley (1980), Baker (1935), Chaudhry (1993), Chauhan & Sharma (1991), Cheng Tso-hin (1987), Collar & Andrew (1988), Duke (1989, 1990, 1994), Garson (1989), Gaston (1980a), Gaston, Garson & Hunter (1981, 1983), Gaston, Garson & Pandey (1993), Gaston, Hunter & Garson (1981), Gaston, Islam & Crawford (1983), Islam (1987, 1991), Islam & Crawford (1986, 1987, 1993), Kaul (1989), King (1978/79), Lamba et al. (1987), Mirza et al. (1978), Narang (1993), Pandey (1991, 1993a), Qadri & Kaul (1990), Roberts (1991), Roles (1990), Sharma & Pandey (1989), Sharma et al. (1990), Vaurie (1965d), Zheng Guang-mei & Zhang Zheng-wang (1993).

109. Satyr Tragopan

Tragopan satyra

French: Tragopan satyre

German: Satyrtragopan

Spanish: Tragopán Sátiro

Other common names: Crimson/Indian Tragopan

Taxonomy. *Meleagris satyra* Linnaeus, 1758, Bengal = Sikkim, India.

Has hybridized in captivity with *Lophura swinhoii*. Monotypic.

Distribution. Himalayas in N India from Garhwal E through Nepal, Sikkim and Bhutan to Assam, Arunachal Pradesh and SE Tibet.

Descriptive notes. Male 67-72 cm (tail 25-34.5 cm), 1600-2100 g; female c. 57.5 cm (tail c. 19.8 cm), c. 1000-1200 g. Males in *Tragopan* with deepest red underparts. Others from *T. temminckii*, the only other with bare blue skin on face, in having lower back, rump and upperwing-coverts brown, rather than crimson. Female dull brown to rufous, with bars and lanceolate markings; tail in particular tends to show obvious blueish-ochraceous skin like male *T. temminckii*, which has much more white on the underparts. First-year male similar to adult female in colour, but markings more like those of adult male.

Habitat. In India, occurs in primary forest between 2400 m and 4750 m. Found in Jamnab and rhododendron forests with dense undergrowth and bamboo, at 2590-3800 m in summer, but down to 2100 m in winter, in Nepal and Bhutan. Upper altitude higher in E than in W of range.

Food and Feeding. Droppings in autumn contained mostly small fragments of leaves and quartz, but also grass and root parts, and an insect wing; invertebrates, such as earwigs, ants, spiders and centipedes, also taken. Usually feeds in early morning and middle to late afternoon. When feeding, associated with small streams; forages in damp areas on moss and leaf litter and even on these items in streams. Also feeds in trees and bushes (e.g. *Berberis*, *Symplocos* and *Rhododendron*) taking young leaves, moss and fruit.

Breeding. Calling at dawn in Mar-Jun; display and copulation observed in mid-May; four fledged young seen at end of May in Nepal. Nest in long tussock grass 10 m from forest edge at 3160 m, in early Jun; another made of old twigs and branches in a tree, placed 6 m above ground, and a third nest similar but closer to ground. 2-3 eggs seen in wild, 4-6 in captivity; incubation usually 28 days in captivity; chicks have dark rufous down above, pale buff below.

Movements. Little definite information, but species claimed to winter 1000-2000 m below breeding altitude. At one locality in Nepal, altitude given as 2230-3550 m, with fledged young observed in May at 2640 m. Apparently moves uphill to feed in the early morning, descending after c. 2 hours. **Status and Conservation.** Not globally threatened. Mace-Land: Vulnerable. Occupies restricted and fragmented habitat within a range of less than 100,000 km², suggesting that total population may number less than 20,000 individuals; probably stable in Bhutan, but declining elsewhere. Suitable habitat lost and fragmented by disturbance and removal of understorey, through livestock grazing and fodder and firewood collection; also by tree-felling and subsequent agricultural use of land. Species is hunted for food. Recorded from several national parks in Nepal: Khaftad, Langtang, Sagarmatha and Maluku Barun. Only current conservation initiative is continuation, since early 1980's, of WPA support for guards and a school at Pipar, in Annapurna Conservation Area in C Nepal. Further surveys are needed, as is improvement of the effectiveness of protection of some key areas. Species has potential to be used as flagship species in awareness programmes concerned with threatened climax forests. CITES III in Nepal.

Bibliography. Ali (1962), Ali & Ripley (1980), Baker (1928), Cheng Tso-hin (1987), Clements (1992), Etchécopar & Hue (1978), Gaston (1980a), Inskipp (1989), Inskipp & Inskipp (1985, 1986, 1993a, 1993b), Kaul & Ahmed (1993), Lamba (1980), Leliot & Yonzon (1980a, 1980b), Roles (1990), Tymstra (1993), Vaurie (1965d), Yonzon (1992), Yonzon & Leliot (1980), Zheng Guang-mei & Zhang Zheng-wang (1993), Zwart (1982).

110. Blyth's Tragopan

Tragopan blythii

French: Tragopan de Blyth German: Blythtragopan Spanish: Tragopán de Blyth
Other common names: Grey-bellied Tragopan

Taxonomy. *Cerionis Blythii* Jerdon, 1870, Nagaland, India.

Race *molesworthi* only known from three specimens. Two subspecies recognized.

Subspecies and Distribution.

T. b. blythii (Jerdon, 1870) - now largely confined to Nagaland, NE India. Historically reported from Manipur (NE India), Burma and SC China (NW Yunnan); may still occur in these areas in small numbers.

T. b. molesworthi Stuart Baker, 1914 - E Bhutan (known only from skins of two males and one female).

Descriptive notes. Male 65-70 cm (tail 18-22 cm), c. 1930 g; female c. 58 cm (tail c. 17 cm), 1000-1500 g. Male is only *Tragopan* with red breast and pale smoky grey belly; bare facial skin yellow, as in *T. caboti*, which has no bright red in plumage. Female darker than other *Tragopan* females, with a lanceolate buff marking on each feather of back. First-year male similar to adult female in general colour, but with red on neck. Male of race *molesworthi* differs from nominate in smaller size, with red restricted to upper breast; also in darker upperparts and paler underparts.

Habitat. Densely wooded valleys and hillsides between 1800 m in winter and 3300 m in summer. The three *molesworthi* specimens were taken in forest of thick shrubs and ringal bamboo at 2400-2650 m.

Food and Feeding. Few observations. Diet believed to consist of a variety of seeds, berries, fruits and buds. The single female specimen of race *molesworthi* was collected foraging in rhododendron forest undergrowth; the crop contained fern fronds, leaves of *Spirea*, *Herpospermum caudigerum* (Cucurbitaceae), Ranunculaceae and other leaf, shoot and petiole material; no animal matter; in captivity invertebrates are taken, as, apparently, are frogs.

Breeding. Apparently from early Apr to mid-May. No nests described, but the Nagas say nest is placed in tree, stump or bush, 2-6 m above ground level; made of sticks, lined with twigs and grass. Local people also state clutch is 2-5 eggs (2-6 in captivity); incubation 28-30 days (in captivity); chicks have pale rufous down above, paler below.

Movements. Seasonal movements stated to be small, as weather extremes are not very marked. Recorded at 1500 m in winter, and in moist temperate montane forest at 1800-3000 m in summer. Makes daily foraging trips up hills; locals apparently set snares along well worn trails.

Status and Conservation. RARE. Mace-Land: *blythii* endangered; *molesworthi* insufficient information. CITES I. Little up-to-date information available, due to inaccessibility of NE India and Burma. Species occurs in Eastern Himalayas Endemic Bird Area. Due to restricted range and probably fragmented habitat, total population may number only 500-5000 individuals, and declining. Present in 3 wildlife sanctuaries in Nagaland, NE India. Habitat loss through tree-felling and conversion to agriculture, and hunting for food are main threats known. Status of *molesworthi* unknown, but extensive forest in Bhutan appears to be fairly secure. No specific conservation actions taken in the wild; surveys, education to reduce overexploitation and improved efficiency of protected areas are needed. A studbook for the captive population is maintained by WPA.

Bibliography. Ali & Ripley (1980), Assink & Coles (1989), Baker (1928, 1935), Biswas (1968), Cheng Tso-hin (1987), Collar & Andrew (1988), Etchécopar & Hue (1978), Gaston (1980a), He Fen-qi & Lu Xie-zhen (1990), He Fen-qi *et al.* (1990), Howman (1984), Inskipp & Inskipp (1993b), King (1978/79), Lamba (1980), Meyer de Schauensee (1984), Roles (1990), Smythies (1986), Zeliang (1980, 1987), Zheng Guang-mei & Zhang Zheng-wang (1993).

111. Temminck's Tragopan

Tragopan temminckii

French: Tragopan de Temminck German: Temmincktragopan Spanish: Tragopán Cariazul
Other common names: Crimson-bellied Tragopan

Taxonomy. *Satyra Temminckii* J. E. Gray 1831, Sichuan, China.

Monotypic.

Distribution. E Himalayas from Arunachal Pradesh SE to NE Burma and N Vietnam, and N to C China.

Descriptive notes. Male c. 64 cm (tail 18.5-23 cm), 1362-1447 g; female c. 58 cm (tail c. 17.5 cm), 907-1021 g. Male is *Tragopan* with most red above and below; large pearl grey spots on underparts characteristic. Female rufous to greyish brown, mottled black above and pale brown with black patches and large oval whitish spots below. First-year male similar to adult female in colour, but with some black and red.

Habitat. Inhabits dense evergreen or mixed forest and thick bamboo and rhododendron. Above 2500 m in NE Burma.

Food and Feeding. Diet consists mostly of flowers, leaves, grass stalks, ferns, bamboo sprouts, mosses, berries and seeds of a wide variety of plant species (46 species recorded); some insects also taken. In early winter, seen feeding among branches of rowan and viburnum trees; crops of 2 birds contained 95% (dry weight) of these fruits. In late winter, birds dig in snow with bill, and feed mainly on grass stalks and ferns, including *Rumex*, *Poa annua* and *Dryopteris*.

Breeding. Laying from early May. Nest of dry leaves and branches, lined with feathers; 8 confirmed nests, all in trees 0.5-8 m above the ground. Clutch size 3-5, with eggs laid every other day; incubation 26-28 days, by female alone; chicks have dark rufous down above, pale buff below. Female raises chicks.

Movements. Only information is from Gaoling Mts in Yunnan, SC China, where birds are reported to descend from 2700-3500 m in summer to c. 2000 m in winter.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Widely distributed; successive surveys have reported new localities, and further sites believed to exist in Hubei, Hunan, Guizhou and S Qinghai. However, no recent records from Tibet, Burma or Vietnam; a single female recently seen in Meihao Wildlife Sanctuary in Arunachal Pradesh, NE India; 2 records from Bhutan, both in 1989. Population may number over 100,000 individuals, an estimate based on fieldwork and surveys in some parts of range, and an estimation of extent of habitat available elsewhere. Species declining due to habitat loss and degradation by overgrazing and understorey cutting; also reportedly hunted and eggs collected. Recorded from over 30 protected areas in W Hubei, W Hunan, N Guangxi, Sichuan, Guizhou, S Shaanxi and SE Gansu, in China, as well as Meihao Wildlife Sanctuary in NE India.

(1989b), Lamba (1980), Li Xiang-tao (1986, 1987a, 1987b), Li Xiang-tao & Lu Xiao-yi (1990), Ludlow & Kinnear (1944), Meyer de Schauensee (1984), Rimlinger (1984), Roles (1990), Smythies (1986), Vaurie (1965d), Zheng Guang-mei & Zhang Zheng-wang (1993), Zwart (1982).

112. Cabot's Tragopan

Tragopan caboti

French: Tragopan de Cabot German: Cabotttragopan Spanish: Tragopán Chino
Other common names: Chinese/Yellow-bellied Tragopan

Taxonomy. *Cerionis Caboti* Gould, 1857, China.

Two subspecies recognized.

Subspecies and Distribution.

T. c. caboti (Gould, 1857) - SE China (Guangdong NE to Zhejiang).

T. c. guangxiensis Cheng & Wu, 1979 - SC China (NE Guangxi).

Descriptive notes. Male c. 61 cm (tail c. 21 cm), 1400 g (one bird); female c. 50 cm (tail c. 16 cm), c. 900 g. Male is only *Tragopan* with buff breast, and is palest overall. Female mottled black and rufous brown above, greyish brown below with whitish triangular markings. First-year male similar to adult female in colour, but with some black and red.

Habitat. Evergreen deciduous forest and mixed deciduous-coniferous forest between 800 m and 1400 m.

Food and Feeding. A recent radio-tracking study found that in winter species frequents areas rich in nuts of *Lithocarpus* and *Cyclobalanopsis* and seed capsules of *Schima superba*; after dawn and before dusk birds seen feeding on leaves of the tree *Daphniphyllum macropodum*; 45% of other encounters were of birds feeding in this tree, 48% feeding on the ground and 7% in other trees. Race *guangxiensis* feeds mostly on seeds of *Castanopsis*, *Moghania*, etc.; also takes red beans.

Breeding. Mar-May. Number of birds nesting appears to vary between years; of 15 nests, 11 were at forest edge, mostly in pine *Pinus taiwanensis*, and earliest was found in early Apr. Lays 3-5 eggs (2-6); chicks have dark rufous down above, darker on head, very pale buff below. Female raises brood. Of 15 nests, 13 were lost, 9 to predation, 2 to bad weather (snow fall during egg-laying or continuous rain during incubation) and 2 to other causes.

Movements. In Wuyanling Natural Reserve, Zhejiang, SE China, little vertical movement detected: occurs at 800-1400 m in summer and 800-1000 m in winter. Radio-tracking in Nov-Dec revealed altitudinal movement of less than 300 m.

Status and Conservation. ENDANGERED. Mace-Land: *caboti* vulnerable; *guangxiensis* endangered, CITES I. Species has restricted range and occurs in Fujian Mountains Endemic Bird Area. Fragmented habitat; suggested population of middle thousands, which is thought to be declining. Occurs in at least 4 natural reserves, including Wuyanling Natural Reserve, SE China, where studied by Zheng Guang-mei and team from Beijing Normal University for over 10 years; information collected on densities, habitat, nesting and other aspects is sufficient basis for management where needed. Species threatened by logging and agricultural encroachment, as well as hunting for food, outside protected areas. Very little known about *guangxiensis*.

Genus *PUCRASIA* G. R. Gray, 1841

113. Koklass Pheasant

Pucrasia macrolopha

French: Eulophe koklass

German: Koklasfasan

Spanish: Faisán Koklas

Other common names: Koklass

Taxonomy. *Satyra macrolopha* Lesson, 1829, Almora Hills, Kumaon, India.

Race *bethelae* may be a clinal form of *biddulphi*. Many races regarded as intergrades, raising doubts about validity of subspecific taxonomy; a morph of race *darwini* without chestnut band on underparts was considered a different race, "*stryani*". Ten subspecies usually recognized.

Subspecies and Distribution.

P. m. castanea Gould, 1855 - E Afghanistan E to Pakistan (Chitral).

P. m. biddulphi Marshall, 1879 - Kashmir.

P. m. bethelae R. L. Fleming, 1947 - NW India (Kulu Valley).

P. m. macrolopha (Lesson, 1829) - W. Himalayas, from Kashmir to Kumaon.

P. m. nipalensis Gould, 1855 - W Nepal.

P. m. meyeri Madarász, 1886 - SC China (W & SW Sichuan E to NW Yunnan); extinct in SE Tibet.

P. m. ruficollis David & Oustalet, 1877 - C China (S Gansu, Shaanxi and W Sichuan).

P. m. xanthospila G. R. Gray, 1864 - NE China (Shaanxi NE through W Hebei and SE Inner Mongolia to SW Manchuria).

P. m. joreitiana Heude, 1883 - CE China (Anhui).

P. m. darwini Swinhoe, 1872 - C & E China (Hubei, SE Sichuan, Zhejiang and Fujian); extinct in NW Fujian and N Guangdong.

Descriptive notes. Male 58-64 cm (tail 22-28 cm), 1135-1415 g; female 52-56 cm (tail 17-19.5 cm), 930-1135 g. Medium-sized pheasant with fully-feathered face in both sexes; full crest and lanceolated plumage of male are characteristic. Female brown, marked with black, with pale grey to rufous tinge according to race; crest very short and pale. Immature, including first-year male, similar to adult female. Races vary mainly in extent of chestnut, black and yellowish in plumage

mainly grass, ferns and moss, as well as seeds and fruits of Solanaceae, and seeds and tender needles of pine, spruce and other plants. Gut contents of 29 specimens of *joreitiana* contained mainly young grass and fern leaves and some seeds.

Breeding. Calling at dawn (lasting 5-50 minutes depending on season) Nov-Jun. Little firm evidence, but believed to nest in Apr-Jun, although one nest found in mid-Jul. Incubation 26-27 days in captivity; no information from the wild.

Movements. In Himachal Pradesh (NW India), downward movements of 1000 m have been recorded in winter. It is suggested that, as snowfall is lighter in E than in W, species may not descend so far in E Himalayas.

Status and Conservation. Not globally threatened. Mace-Land: *nipalensis/macrolophacastanea/biddulphi/bethelae* safe; *joreitiana/darwini* vulnerable; *meyeriruficollis/xanthospila* vulnerable. Probably still widespread, but habitat increasingly destroyed and fragmented, resulting in many small populations, often at low densities. Seems to prefer forest with heavy understorey, and this is being degraded by overgrazing and collection of wood for fuel, and by other forms of disturbance (agricultural encroachment, logging, etc.); all of these factors are problems. Hunting is also probably a threat in some areas. No specific conservation initiatives, but species occurs in several protected areas. Two subspecies clusters may warrant conservation attention: *joreitiana* and *darwini*, which have a combined range of less than 50,000 km² in SE China, and for which only anecdotal information exists; and *meyeriruficollis* and *xanthospila*, which comprise central block of races, and which are similarly little known. Baseline surveys to assess status and distribution of birds and habitat are first step.

Bibliography. of males; race *darwini* has two morphs in parts of range, based on presence or absence of chestnut band on underparts; intermediate birds occur.

Habitat. Coniferous and mixed forests in steep terrain, down to 2000 m in winter, and as high as tree-line at 3000-4000 m in spring. Areas with dense bamboo and understorey.

Food and Feeding. Rarely seen foraging because flushes so quickly, but produces deep feeding scrapes on forest floor. Believed to eat variety of seeds, including acorns, berries and buds; also insects and worms. Droppings in autumn and gut contents of 3 birds contained

Genus *LOPHOPHORUS* Temminck, 1813

114. Himalayan Monal

Lophophorus impejanus

French: Lophophore resplendissant **German:** Rostschwanzmonal **Spanish:** Monal Coliriojo
Other common names: Impeyan Monal, Himalayan Monal-pheasant/Pheasant

Taxonomy. *Phasianus impejanus* Latham, 1790, India.

Forms superspecies with *L. sclateri*. Monotypic.

Distribution. E Afghanistan E along Himalayas to Bhutan and NE India, and N into S Tibet; also reported as occurring in Burma.

Descriptive notes. 63-72 cm; 1800-2380 g. Male differs from those of other monals by peculiar wiry crest and entirely rufous tail; chestnut wings and (normally) white rump very conspicuous in flight. Variation among males in several traits; green-breasted, dark-rumped morph frequent in Kashmir. Female differs from those of other monals especially in pattern on underparts and colour of tail barring; also has more or less prominent crest, and generally rather more uniform plumage. Immature similar to female but with markings somewhat less distinct.

Habitat. Inhabits open coniferous or mixed forests with rhododendron and bamboo, usually in steep valleys; also recorded in and around cultivation in some areas. Above tree-line in summer, but down to 2500 m and lower in winter; altitudinal range 2100-4500 m.

Food and Feeding. Diet apparently varies according to locality, but includes seeds, tubers, shoots, berries (e.g. *Cotoneaster microphylla*), insects and their larvae; terrestrial insects and tubers believed to make up most of food taken. Digs extensively with bill, up to depth of 25 cm, creating distinctive dug-over areas on hillsides. In Nepal, 26 droppings contained only vegetable matter. Species forages throughout day.

Breeding. Dawn calling occurs sporadically throughout most of year, but perhaps more predictably in Jan-Jun; display by males observed in Apr. May and once in Sept. at any time of day. In India, egg records from mid-Apr to late June. Breeding can occur at various altitudes, but upper altitudes believed to be far more typical. Nest is a simple scrape under some feature, such as a bush, on a steep hillside; often unlined. Normally 3-5 eggs (2-8), with records of larger clutch size considered suspect; incubation 27 days (in captivity); chicks have chocolate and rufous down above, dirty white below with darker flanks.

Movements. Believed to show greatest altitudinal movement of all Himalayan pheasants. In Himachal Pradesh, NW India, above 3000 m in summer and at 2000-3000 m in winter; in Nepal descends from summer altitude of 4350 m to 3200 m in winter. Possibly performs less movement in E of range. See page 461.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. CITES I. A widely distributed species that is still common throughout its range in suitable habitat. In some areas of Kulu Valley in Himachal Pradesh, NW India, over 70 individuals encountered per 100 hours of fieldwork. National bird of Nepal, where considered a common resident; at Pipar in WC Nepal, a population of 6-9 pairs was estimated in a 1.5 km² study area, giving density of 4-6 pairs/km². Recorded from several sites in Tibet, at edge of range; occurred throughout Bhutan in 1930's, where probably still widespread. Recorded from many protected areas. Tree harvesting and general degradation of habitat are problems in many areas, as is overexploitation for food. In Kulu Valley, male's crest was sought in order to adorn hats, but this practice seems to have become much less common during last 10 years.

Bibliography. Ali (1962), Ali & Ripley (1980), Baker (1928, 1930, 1935), Bales & Lowther (1952), Bisht *et al.* (1990), Catlow (1982), Chaudhry (1993), Cheng Tso-hin (1987), Clements (1992), Etchécopar & Hue (1978), Gaston (1980a), Gaston, Garson & Hunter (1981a, 1981b, 1983), Gaston, Garson & Pandey (1993), Gaston, Lelliott & Ridley (1982), Howman & Garson (1993), Inskipp (1989), Inskipp & Inskipp (1985, 1986, 1993a, 1993b), Kaul & Ahmed (1993), Lamba (1980), Lamba *et al.* (1987), Lelliott & Yonzon (1980a, 1980b), Pandey (1993a), Qadri *et al.* (1990), Roberts (1991), Sathyakumar *et al.* (1993), Sharma & Pandey (1989), Smythies (1986), Tang Chan-zhu (1990), Timsira (1993), Vaurie (1965d), Yahya (1993a), Yin (1970), Yonzon & Lelliott (1980), Zheng Guang-mei & Zhang Zheng-wang (1993).

115. Sclater's Monal

Lophophorus sclateri

French: Lophophore de Sclater **German:** Weißschwanzmonal **Spanish:** Monal Coliblanco
Other common names: Crestless Monal, Sclater's Monal-pheasant/Pheasant

Taxonomy. *Lophophorus sclateri* Jerdon, 1870, Mishmi Hills, north-east India.

Forms superspecies with *L. impejanus*. Proposed race *orientalis*, for eastern populations, not widely accepted. Monotypic.

Distribution. NE India and SE Tibet to NE Burma and SC China (W Yunnan).

Descriptive notes. 63-68 cm; male c. 2500 g, female 2126-2267 g. Male differs from other monals by extensive white from middle back down onto uppertail-coverts, and crest reduced to short, curly feathers. Female crestless, with underparts vermiculated, rather than streaked, and full barring on tail. Immature male resembles adult female, but has darker mantle, whiter rump, and some cinnamon on tail feathers. White on tail of males narrower in E (proposed race *orientalis*) than in W.

Habitat. In China, occurs between 2500 m and 4200 m, in coniferous forest with bamboo understorey, and in subalpine rhododendron scrub. In Burma, believed to remain above tree-line, not descending below 3000 m.

Food and Feeding. Very little known; *Polygonum* seeds and thistle or hard-headed flower heads are only food items specifically mentioned.

Breeding. Birds collected in Tibet in mid-May were in breeding condition; no reliable data on nest, clutch size or incubation; more than one clutch of 5 eggs reported. No further information available.

Movements. No movements described, but species may perform some kind of altitudinal movement according to season.

Status and Conservation. RARE Mace-Lande: Endangered. CITES I. Little up-to-date information available, due to remoteness of range. Occurs in Eastern Himalayas Endemic Bird Area. Due to restricted range and probably fragmented habitat, total population

may number fewer than 10,000 individuals; believed to be stable in China, declining elsewhere. Locally common in Gaoligong Shan Natural Reserve in Yunnan. Possible threats are habitat degradation, and overexploitation of species for food. No specific conservation actions under way in the wild; surveys, education to reduce overexploitation and improved efficiency of protected areas are needed.

Bibliography. Ali & Ripley (1948, 1980), Baker (1928, 1930, 1935), Cheng Tso-hin (1987), Collar & Andrew (1988), Davison (1974, 1978b), Etchécopar & Hue (1978), Gaston (1980a), He Fen-qi & Liu (1991), He Fen-qi *et al.* (1990), King (1978/79), Lamba (1980), Ludlow & Kinnear (1944), Meyer de Schauensee (1984), Roles (1990), Smythies (1986), Tang Chan-zhu (1990), Zheng Guang-mei & Zhang Zheng-wang (1993).

116. Chinese Monal

Lophophorus lhuysii

French: Lophophore de Lhuys **German:** Grünschwanzmonal **Spanish:** Monal Coliverde

Taxonomy. *Lophophorus lhuysii*, Geoffrey St Hilaire and Verreaux, 1866, Moupin, China. Monotypic.

Distribution. C China, in Sichuan, Gansu and Yunnan; no recent records from NW Sichuan, Qinghai or Tibet.

Descriptive notes. 75-80 cm; c. 3008 g. Noticeably larger and more heavily built than other monals, with much stouter bill. Male has droopy crest; no rufous or chestnut in tail feathers, which are mainly glossy blue-green. Female has fairly narrow rufous and black barring on tail and more white on lower back than other female monals.

Habitat. Inhabits subalpine and alpine meadows with bare rock outcrops; mainly occurs at c. 3000-4900 m.

Food and Feeding. Feeds on roots, bulbs, leaves and flowers, including *Anemone rivularis*, *Caltha palustris*, *Primula*, *Allium pratin-*

and *Aconitum tatsienense*, *Fritillaria* bulbs have been stated as major food in one study, minor part in another. Some insects are also taken. In winter, roots of perennial herbs, seeds and occasionally mosses are eaten.

Breeding. Season Mar-June, apparently earlier than other alpine pheasants in Sichuan, China. Nests found at 3800-4000 m, beside crags; at 3900 m, temperature in Apr is 4-7° C, falling to -10° C, with plenty of snow. Single sex flocks seen during breeding period when more than 1 pair in an area. Recorded nests contained 3-5 eggs; incubation 28 days, by female only. Individuals may not breed every year.

Movements. No seasonal movements; despite claims that species moves downhill in winter, evidence shows that it remains at same altitude all year round.

Status and Conservation. ENDANGERED Mace-Lande: Vulnerable. CITES I. Object of study by He Fen-qi of Academia Sinica, Beijing, a study made all the more difficult by remoteness of range; occurs in Eastern Himalayas Endemic Bird Area. Much of species' high altitude range is uninhabitable for humans, and therefore relatively safe. Due to restricted range and probably patchy habitat, total population roughly estimated at 5000-10,000 individuals, although declining slightly. Present in natural reserves in 7 counties in Sichuan. Threats are degradation of habitat and overexploitation of species for food. Captive breeding programme initiated by Endangered Species Breeding Centre in Beijing and San Diego Zoo in USA.

Bibliography. Cheng Tso-hin (1987), Collar & Andrew (1988), Deng Wei-je (1990), Etchécopar & Hue (1978), He Fen-qi & Cui Xie-zhen (1990b), He Fen-qi & Lu Jia-shun (1988), He Fen-qi, Lu Jia-shun & Xie Xian-hua (1989), He Fen-qi, Lu Tai-chun *et al.* (1986), Huang Shi-guang & Lu Fu-jin (1986a), King, B.J. & Peng Ji-jun (1991), King, W.H. Genus *GALLUS* Brisson, 1760

117. Red Junglefowl

Gallus gallus

French: Coq bankiva **German:** Bankivahuhn **Spanish:** Gallo Bankiva
Other common names: Wild Junglefowl

Taxonomy. *Phasianus Gallus* Linnaeus, 1758. Poulo Condor, south Vietnam.

Forms superspecies with *G. sonneratii* and *G. lafayetii*; hybridizes locally with *G. sonneratii* in areas of contact. Intergradation occurs between at least three of the accepted races. Five subspecies usually recognized.

Subspecies and Distribution.

G. g. murghi Robinson & Kloss, 1920 - N & NE India, adjacent Nepal and Bangladesh.

G. g. spadiceus (Bonaterre, 1791) - CS China (SW Yunnan), Burma, Thailand (not E), Peninsular Malaysia and N Sumatra.

G. g. jabouillei Delacour & Kinnear, 1928 - CS China (SE Yunnan, Guangxi and Hainan), N Vietnam.

G. g. gallus (Linnaeus, 1758) - E Thailand through Kampuchea and C & S Laos to C & S Vietnam.

G. g. bankiva Temminck, 1813 - S Sumatra, Java and Bali.

Also occurs in Philippines, Sulawesi and parts of Lesser Sundaes, where probably introduced. Introduced or feral in many areas, including throughout Micronesia, Melanesia and Polynesia; on Reunion and the Grenadines; probably also in New Zealand and South Africa.

Descriptive notes. Male 65-75 cm, 672-1450 g; female 42-46 cm, 485-1050 g. Male differs from that of *G. lafayetii* in form of comb and by absence of heavy streaking in plumage. Female differs from those of *G. sonneratii* and *G. lafayetii* by lack of bold pattern on underparts; and from those of *G. lafayetii* and *G. varius* by lack of bold pattern on flight-feathers. Immature male similar to adult female, but with red on back, and has larger, yellow neck hackles. Variation between races is most noticeable in colour, length and shape of male hackles during breeding season: redder and rounded in *bankiva*; pointed and with dark

markings in *murghi*; race *jabouillei* is somewhat intermediate, with smaller comb and hackles, and no white ear lobe; female *jabouillei* generally rather darker than nominate female.

Habitat. Throughout extensive range, occupies most tropical and subtropical habitats, including mangroves, from sea-level up to c. 2000 m. Seems to prefer flat or gently sloping terrain and edge or secondary habitats to forest.

Food and Feeding. Opportunistic and omnivorous; probably shows seasonal preferences, depending upon availability. Gut contents of 37 birds in India contained seeds of 30 species and many invertebrate taxa; plant genera taken include *Trichosanthes*, *Rubus*, *Carissa*, *Zizyphus* and *Shorea*; only cultivated plant species was rice (*Oryza*). Similarly wide range of food items found in 23 crops from Thailand, including fruits of Euphorbiaceae, bamboo seeds, and *Zizyphus* fruits. Insects recorded include ants, beetles and termites (nearly 1000 in one crop) and their eggs.

Breeding. Mar-May, during dry season, in India, although eggs found Jan-Oct in different parts of the country; Mar-Jun in Bangladesh; Dec-May (peaking Jan-Feb) in Malay Peninsula; Feb-May in China, where earliest records are from S Yunnan. Polygamous. Nests found in many sites, but typically in dense secondary growth or bamboo forest, and situated under bushes or in clumps of bamboo. Usually 5-6 eggs (4-9); incubation 18-20 days, by female only; chicks have maroon-brown down above, whitish buff below, browner on breast.

Movements. No movements described. Presumably none undertaken, as extremes of climate are limited in most of range; nevertheless, in N Thailand, birds apparently descend to lower altitudes in winter.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Species distributed over large range and occurs in variety of habitats, including secondary vegetation and man-made habitats, such as rubber and oil palm plantations. In Thailand, considered widespread and common, with estimated population in hundreds of thousands, despite relentless persecution. In Indonesia, still widespread but declining due to habitat loss and degradation, and also hunting; not particularly common in Java, Sulawesi (where heavily hunted) or Lesser Sundaes, but rather common in Sumatra. In India, considered stable in protected areas, but declining elsewhere due to habitat degradation and overhunting for food. Locally common in Nepal, where reported from several localities, e.g. Sukla Phanta, Bardia, Chitwan and Kosi Tappu, but few records elsewhere, and species believed to have declined in recent years; has apparently been shot out in some areas. Known from protected areas throughout range. Not protected by Indonesian law.

Bibliography. 118. Grey Junglefowl

Gallus sonneratii

French: Coq de Sonnerat

German: Sonnerathuhn

Spanish: Gallo Gris

Other common names: Sonnerat's Junglefowl

Taxonomy. *Gallus Sonneratii* Temminck, 1813, India.

Forms superspecies with *G. gallus* and *G. lafayetii*; hybridizes locally with *G. gallus* in areas of contact. Monotypic.

Distribution. Peninsular India, S from Gujarat, S Rajasthan, Madhya Pradesh and mouth of R Godavari in Andhra Pradesh.

Descriptive notes. Male 70-80 cm, 790-1136 g; female c. 38 cm, 705-790 g. Male generally much greyer than congeners, with rather small comb and hackles, and very distinctive neck pattern. Female differs from those of other *Gallus* by combination of white streaks on breast and unbarred flight-feathers. Immature similar to female; young male soon shows characteristic grey and rusty feathers of adult male.

Habitat. Affects understorey and scrubby parts of evergreen, mixed and deciduous forest, up to 1500 m; also frequents cultivation and abandoned plantations of rubber, coffee and tea, especially where overgrown with *Lantana*; often seen in clearings or along paths.

Food and Feeding. Diverse diet, including seeds of bamboo and *Strobilanthes* among others, shoots of grass and crops, tubers, figs and berries of *Zizyphus*, *Lantana*, *Streblus*, etc. Animals eaten include insects (e.g. grasshoppers and termites) and even small reptiles. Appears to forage

chicks.

Movements. No movements described; some may occur in response to seasonal availability or abundance of local food sources.

Status and Conservation. Not globally threatened. Mace-Lande: Vulnerable. CITES II. Little information on status despite extensive distribution. Believed to be declining, with populations increasingly fragmented, in Kerala at least. Threatened by loss of forested habitats to agriculture, and also by overgrazing and burning of scrub. Hunted for food in some areas; hackles are used in fly-fishing, but demand seems to be satisfied from captive birds. Occurs in more than 10 protected areas in Rajasthan, Madhya Pradesh, Gujarat, Kerala and Tamil Nadu, including Mount Abu and Anamalais Wildlife Sanctuaries, and Vansda, Silent Valley and Eravikulam National Parks. Some studies under way; information required upon which to base management regime.

Bibliography. Ali & Ripley (1980), Baker (1928, 1930), Collias & Collias (1967), Coote (1992), Danforth (1958), Gautam (1992), Johnson (1964), Morejohn (1968a, 1968b), Uttangi (1993), Zacharias & Gaston (1993).

119. Ceylon Junglefowl

Gallus lafayetii

French: Coq de Lafayette

German: Ceylonhuhn

Spanish: Gallo de Ceilán

Other common names: La Fayette's Junglefowl

Taxonomy. *Gallus Lafayetii* Lesson, 1831, India; error = Sri Lanka.

Forms superspecies with *G. gallus* and *G. sonneratii*. Proposed race *xanthimaculatus* not currently accepted. Monotypic.

Distribution. Sri Lanka.

Descriptive notes. Male 66-72 cm, 790-1140 g; female c. 35 cm, 510-625 g. Male has most of plumage boldly streaked; distinctive yellow patch on comb. Female much smaller, with characteristic combination of white markings on underparts and boldly barred wings. Immature male similar to adult female, but with some markings similar to those of adult male.

Habitat. Coastal scrub to mountain forest, from sea-level up to 2000 m.

Food and Feeding. Eight birds shot in Mar had wide variety of food remains in gut, including grass seeds, seed pods, berries and flower petals, scarab beetles, termites, mol-

luses, woodlice and ticks; termites and grass seeds common. Commonly seen foraging along open tracks through forest in mornings and evenings, especially after rain. Foraging tends to be curtailed by midday heat.

Breeding. Eggs apparently found in all months, with Feb-May most usual; in N Sri Lanka, Feb-Aug; in E, at Batticaloa, Feb-Oct. Nests in a variety of locations, typically on ground amongst bushes, under logs, etc.; will use deserted squirrel nests; also recorded in old crow nest, c. 10 m above ground level. Clutch usually 2 eggs (2-4); larger clutches (of up to 9 eggs) reported, but believed to be multiple clutches, laid by more than 1 female; incubation in captivity 20-21 days; downy chicks similar to those of *G. gallus*, with darker markings.

Movements. Believed to be sedentary, although fruiting *Strobilanthes* apparently attracts birds from a long distance to feed.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. No recent information on status. Apparently tolerates human disturbance and habitat degradation well. Species has restricted range and occurs in Sri Lanka Endemic Bird Area.

Bibliography. Ali & Ripley (1980), Baker (1928, 1930), Collias & Collias (1967), Deraniyagala (1957), Henry (1971), Morejohn (1968a), Phillips (1978), da Silva *et al.* (1993).

120. Green Junglefowl

Gallus varius

French: Coq de Java

German: Gabelschwanzhuhn

Spanish: Gallo de Java

Other common names: Javan Junglefowl

Taxonomy. *Phasianus varius* Shaw, 1798, Java.

Formerly included in monospecific genus *Ceagrus*. Monotypic.

Distribution. Java and neighbouring islands of Lesser Sundaes E to Flores, Sumba and Alor.

Descriptive notes. Male c. 70 cm, female c. 40 cm; 454-795 g. Male unmistakable, with appearance of scaling. Different colours over most of dark green plumage; multicoloured comb and hackles distinctive. Female differs from those of other *Gallus* by combination of scaly upperparts, barred wings and lack of bold pattern on breast. Immature resembles female.

Habitat. Coastal areas and low-lying valleys, but also found in inland forest. Inhabits forest margins and scrub around rice plantations and other cultivation, from sea-level up to over 2000 m.

Food and Feeding. Very little known, but believed to feed on insects and weed seeds and to visit grain fields regularly. In captivity consumes seeds, berries, leaves, fruit, insects and worms.

Breeding. Little reliable information available, but season believed to be long and variable in Java; usually Jun-Nov; 16 nest records for period Mar-Nov, with 8 in May-Jun; earlier in E Java than in W. Nest is a depression in ground among dense vegetation; occasionally placed atop a tree-fern. Data on clutch size are unreliable, with claims of average 8 eggs (6-12) probably too high, and 3-4 eggs more likely; incubation in captivity 21 days; chicks have chocolate brown down above, creamy white below, with brown neck and breast.

Movements. No movements described.

Status and Conservation. Not globally threatened, Mace-Lande: Safe. Occurs in a variety of habitats, including secondary vegetation and man-made habitats, e.g. coffee plantations, and therefore not of immediate conservation concern. Widespread throughout range and found near human

settlements in heavily populated areas on Java. Found in many protected areas of various designations, but such areas may not be essential for long-term survival of species. At present, most important conservation requirement is cessation of overexploitation of wild populations, as species is trapped extensively for pet trade; species is hybridized with domestic fowl, and male offspring are much prized for vocal competitions; this activity was once the practice exclusively of inhabitants of Kangean Is (off NE Java), but entire villages along N coast of Bali now pursue this same activity, with result that many males are now being removed from populations; in 1980, the hybrid, known locally as *hekisar*, was declared provincial bird of East Java, resulting in an increase in trade.

Bibliography. van Balen & Holmes (1993), Delacour (1978), Holmes (1989, 1991), Hoogerwerf (1949), Howman (1993), MacKinnon (1988), MacKinnon & Phillpotts (1993), Morejohn (1968a), Stemer (1945), Sumatjda (1981), Wayne (1969), White & Bruce (1986)

Genus *LOPHURA* Fleming, 1822

121. Kalij Pheasant

Lophura leucomelanos

French: Faisan leucomèle

German: Kalifasan

Spanish: Faisán Kálif

Other common names: Kalij

Taxonomy. *Phasianus leucomelanos* Latham, 1790, India.

Forms a superspecies with *L. nychthemera*. Formerly included in genus *Gemnaeus*. Races *oatesi*, *lineata* and *crawfordi*, forms to E of R Irrawaddy in Burma, are more closely related to some races of *L. nychthemera* than to other races of present species to W of Irrawaddy; revision of these two species needed. Several races of dubious validity: *horsfieldii* is a synonym of *lathamii*. Specific status has been proposed for races *lathamii* and *lineata*. Nine subspecies currently recognized.

Subspecies and Distribution.*L. l. hamiltoni* (J. E. Gray, 1829) - W Himalayas, from R Indus E to W Nepal.*L. l. leucomelanos* (Latham, 1790) - W & EC Nepal.*L. l. melanota* (Hutton, 1848) - NE India (Sikkim) and W Bhutan E to R Sankosh.*L. l. moffitti* (Hachisuka, 1938) - described from captive birds; only reliable record in wild from C Bhutan.*L. l. lathamii* (J. E. Gray, 1829) - E Bhutan and NE India (Assam) E to Burma (probably E to R Irrawaddy).*L. l. williamsi* (Oates, 1898) - W Burma, E to R Irrawaddy; possibly also in NE India (E Manipur).*L. l. oatesi* (Ogilvie-Grant, 1898) - Arrakan Yomas in S Burma, E of R Irrawaddy.*L. l. lineata* (Vigors, 1831) - S Burma E of R Irrawaddy S to W Thailand.*L. l. crawfordi* (J. E. Gray, 1829) - SE Burma (Tenasserim) and peninsular Thailand.Introduced (*leucomelanos*) to Hawaiian Is.

Descriptive notes. Male 63-74 cm (tail 21-35 cm), 795-1150 g; female 50-60 cm (tail 19-23.5 cm), 564-1024 g. Male is amongst most variable pheasants; mainly blue, with long crest and scarlet face wattles; legs pale brown, greenish or grey, not crimson as in *L. nychthemera*. Female mostly reddish brown or dark brown with pale markings. Immature dark brown; male assumes adult plumage in 1st year. Considerable variation in male plumage among races, mainly in colour of breast, extent of white markings on lower back, rump and tail; race *hamiltoni* has white crest.

Habitat. Occurs in variety of habitats, from evergreen and deciduous forests with dense undergrowth in valleys to thickets, secondary vegetation and abandoned cultivation; down to altitude of 25 m in NE Bangladesh.

Food and Feeding. Omnivorous. Diet consists of items as diverse as bamboo seeds and small snakes, but especially termites, figs, forest yams and bamboo seeds; other identified items include acorns, ripe *Pyrus* and *Rosa* fruits, *Vicium* stems, *Desmodium* pods, *Dioscorea* bulbils, seeds of *Nyctanthes*, nettle and fern tops and *Polygonum* and *Rubus* fruits. Believed to forage in small groups (possibly family units); usually scratches ground, but can dig for roots and tubers.

Breeding. Considerable variation with race, usually including Apr and May; *hamiltoni* Mar-Jun; *leucomelanos* Apr-Jun; *melanota* Mar-May; *lathamii* Feb-Oct (mostly Apr-May and Jul-Aug); *williamsi* Apr-May (possibly Mar-Jun); *oatesi* Mar-May; *lineata* Feb-Jul. Nest is a slight hollow in thick undergrowth, usually near water. Usually 6-9 eggs (5-10); 14-15 eggs reported, probably laid by more than 1 female; incubation from 20 days in warmer parts, to 22 in cooler, higher areas, by female only; chicks have chestnut and brown down above, whitish below. Male seen leading small chicks.

Movements. Little information. Believed to be sedentary, although some seasonal movement likely in N. Long daily excursions to water sources may occur in some areas.

Status and Conservation. Not globally threatened. Mace-Land: *hamiltoni*, *leucomelanos*, *melanota*, *lathamii*, *williamsi* safe; *moffitti* insufficient information; *oatesi*, *lineata*, *crawfordi* vulnerable. Occurs in variety of habitats, including secondary vegetation, so status not of immediate concern, situation varying with race. Great attention paid to *moffitti* due to paucity of data; known only from birds exported from Calcutta bird market in 1930's (?and 1920's) until seen in Bhutan in early 1993. Very common in NW Indian Himalayas; fairly common in Nepal; rare resident in Bangladesh; no information from Bhutan. Large coveys regularly encountered in autumn at several sites in Himachal Pradesh, NW India; birds may be seen more often in disturbed areas near villages. Threats include loss and degradation of habitat and overexploitation for food.

122. Silver Pheasant

Lophura nychthemera

French: Faisan argenté

German: Silberfasan

Spanish: Faisán Plateado

Taxonomy. *Phasianus nychthemera* Linnaeus, 1758, China.

Forms superspecies with *L. leucomelanos*. Previously placed in genus *Gemnaeus*. Many races of questionable validity, based on plumage patterns of male upperparts; seven races, *rufipes*, *occidentalis*, *ripponi*, *jonesi*, *beaulieu*, *nychthemera* and *fokiensis*, at least, form cline and probably not subspecifically distinct from one another. Fifteen subspecies currently recognized.

Subspecies and Distribution.*L. n. occidentalis* Delacour, 1948 - SC China (NW Yunnan) and NE Burma.*L. n. rufipes* (Oates, 1898) - N Burma in Northern Shan States, between R Irrawaddy and R Salween.*L. n. ripponi* (Sharpe, 1902) - N Burma in Southern Shan States, between R Irrawaddy and R Salween.*L. n. jonesi* (Oates, 1903) - SC China (SW Yunnan), N & C Thailand and Burma (South Shan

States, between R Salween and R Mekong).

L. n. omeiensis Cheng, et al., 1964 - C China (Sichuan).*L. n. rongjiangensis* Tan & Wu 1981 - SC China (SE Guizhou).*L. n. beaulieu* Delacour, 1948 - SC China (SE Yunnan), N Laos and N Vietnam.*L. n. nychthemera* (Linnaeus, 1758) - S China (Guangdong and Guangxi) and N Vietnam.*L. n. whiteheadi* (Ogilvie-Grant, 1899) - Hainan I (S China).*L. n. fokiensis* Delacour, 1948 - SE China (NW Fujian and possibly Zhejiang).*L. n. berliozii* (Delacour & Jabouille, 1928) - C Vietnam, on W slopes of Annamite Mts.*L. n. beli* (Oustalet, 1898) - C Vietnam, on E slopes of Annamite Mts.*L. n. engelbachi* Delacour, 1948 - Bolovens Plateau, S Laos.*L. n. lewisi* (Delacour & Jabouille, 1928) - SW Kampuchea and SE Thailand.*L. n. annamensis* (Ogilvie-Grant, 1906) - S Vietnam.

Descriptive notes. Length very variable with race. Nominate male 120-125 cm (tail 60-75 cm); female 70-71 cm (tail 24-32 cm). Race *lewisi* male c. 67 cm (tail c. 30 cm); female c. 61 cm (tail 23-25 cm). Weight (overall) male 1130-2000 g, female 1150-1300 g. Male (most races) has strikingly contrasting white and bluish black plumage; long crest, scarlet wattles and crimson legs. Female mostly reddish brown or dark brown with pale markings more or less obvious. Immature is brown, finely vermiculated black above; male assumes adult plumage in 2nd year. Considerable variation in male plumage among races.

mainly in extent of black markings on back, rump and tail; birds whitest and with longer tails towards NE; S race *lewisi* darkest, with shortest tail.

Habitat. Variety of forested habitats, in SE of range, mostly above 1000 m; in NW may occur in more open habitats, including grassland bordered by forest, but conflicting information. In Thailand, occurs in both semi-evergreen and hill-evergreen forests. Reportedly in less open areas than *L. leucomelanos*.

Food and Feeding. In Guangdong (S China), 64 plant items and 30 animal species recorded in 13 gut contents taken throughout year; especially seeds and fruits of *Castanopsis chinensis* and *Fagaceae*. Feeds by scratching and occasionally by digging.

Breeding. In China, laying from mid-Mar in C Guangdong, otherwise from Apr onwards; thought to be Mar-May in Upper Burma and Thailand, but little reliable information. In Guangdong, 10 nests averaged 6-9 eggs, but one contained 12, all 12 hatching; chicks appear in wet season (with high temperature and humidity), latest hatching in early Jun. Incubation in captivity 25-26 days; chicks have chestnut and dark brown down above, whitish below. Has bred at 1 year old in captivity.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Land: *annamensis* endangered; *whiteheadi* endangered; *engelbachi* endangered; *lewisi* vulnerable; all other races safe. Widely distributed and seemingly common in suitable habitat, so status not of immediate concern, but several isolated races merit attention. In China, considered common or very common and stable, depending on locality, but some isolated races may be rare and declining; in Thailand, estimated to number tens of thousands, possibly declining. Based on extent of habitat available, *annamensis* in Vietnam estimated to number 500-5000, and likewise *engelbachi* in Laos; *whiteheadi* on Hainan I likely to number less than 10,000, as does *lewisi* on the border between Thailand and Kampuchea. Suffers various forms of habitat loss and degradation and overexploitation for food; particular pressures vary from place to place.

Bibliography. Baker (1928, 1930), Cheng Tso-hin (1963, 1979b, 1987), Cheng Tso-hin et al. (1964), Deignan (1945), Delacour (1948, 1949), Ettemeyer & Hsu (1978), Gao Yu-ren & Liu Zhong-min (1992), Gao Yu-ren & Zhang You-chang (1990), He Fen-qi et al. (1990), Humphreys & Bam (1990), King, B.F. (1989a), Lekagul & Round (1991), Li Bing-hua & Chen Bi-hui (1984), McGowan & Panchen (1994), Meyer de Schauensee (1984), Nguyen Cu & James (1993), Norupuck (1987), Robson et al. 123. Imperial Pheasant

Lophura imperialis

French: Faisan impérial

German: Kaiserfasan

Spanish: Faisán Imperial

Taxonomy. *Hierophasis imperialis* Delacour and Jabouille, 1924, Donghoi, C Vietnam.

Formerly placed in genus *Hienphapsis*. Taxonomic status of three Vietnamese endemic *Lophura* forms, *L. e. edwardsi*, *L. e. hatinhensis* and present species is uncertain. Monotypic.

Distribution. C Vietnam. Alleged occurrence in Laos is probably erroneous.

Descriptive notes. Male c. 75 cm (tail c. 30 cm); female c. 60 cm (tail c. 19 cm). Male entirely dark blue; rather short, pointed, blackish blue crest; feathers of lower back, rump, upperwing coverts and upper tail coverts have bright metallic blue edges. Separated from *L. edwardsi* by dark crest and bluish tinges to upperwing coverts. Female chestnut brown above, pale greyish chestnut below. First-year male dark brown, with some blue on feathers of back; adult plumage attained in 2nd year.

Habitat. A. occurring in collections of C. found pair, rugged limestone. Only other record from secondary lowland forest at 50-100 m.

Food and Feeding. No information available.

Breeding. No information other than from captivity: clutch size 5-7, incubation 25 days.

Movements. No information available.

Status and Conservation. VULNERABLE. Mace-Land: Endangered. CITES I. Only recent record was of live bird trapped by ruffian collectors 12 km W of Cat Bin in Feb 1990; only other reliable record was of a live pair sent by ruffians to J. Delacour in 1973. Historical suggestion that species occurs in C Laos, probably erroneous, and based on vague description of a bird given to local hunters. Species has restricted range, occurs in Annamese Lowland, Isthmic Bird Area. Population now estimated to number 100-1500 birds, based on available information. Suspected to be declining. Probably threatened by overexploitation for food and habitat destruction, rampant poaching and mismanagement needed. University of Hanoi has plan to conduct research on C. Ru area. Contemporary range of species very poorly known and extensive surveys are highest priority.

Bibliography. Carpenter & Bates (1993), Corbin & Bates (1985), Delacour (1924, 1925), A. F. Bennett & King (1978/79), Nguyen Cu & James (1993), Raethel (1988), Robson et al. (1993a), Roles (1990), Wiltschko (1988).

124. Edwards's Pheasant

Lophura edwardsi

French: Faisan d'Edwards German: Edwardsfasan Spanish: Faisán de Edwards
Other common names: Annam Pheasant (*edwardsi*); Vo Quy's/Vietnamese Pheasant/Fireback (*hatinhensis*)

Taxonomy. *Gennaues Edwardsi* Oustalet, 1896, Quangtri, central Vietnam. Formerly placed in either genus *Delacourigallus* or genus *Hierophasis*. Taxonomic status of the three Vietnamese endemic *Lophura* forms, *L. e. edwardsi*, *L. e. hatinhensis* and *L. imperialis* is uncertain and requires revision, but very little material available, and biology and ecology of all three forms very poorly known. Status of form *hatinhensis* particularly uncertain: discovered quite recently, and described as separate species, but on insufficient grounds; only ever known from a small area in Vietnam that is now almost completely deforested; limited data available at present suggest that this form is probably best considered a race of present species, although it can not be discounted that future research might indicate that *hatinhensis* does indeed merit treatment as a separate species. Two subspecies currently recognized.

Subspecies and Distribution.

L. e. hatinhensis Vo Quy, 1975 - NC Annam, C Vietnam.
L. e. edwardsi (Oustalet, 1896) - C Annam, C Vietnam.

Descriptive notes. 58-65 cm; tail length in male and female (*edwardsi*) respectively 24-26 cm and 20-22 cm; one male and one female of nominate *edwardsi* respectively 1115 g and 1050 g, one male of race *hatinhensis* 1100 g. Male distinctive in all black plumage with blue gloss and metallic green fringes to upperwing-coverts, contrasting with fairly small white crest; colouring of crest and upperwing-coverts separates from sympatric *L. imperialis*; male of *L. swinhoi* generally more colourful, and has extensive white on upper back and in tail; *L. leucomelanos hamiltoni* also mainly blackish blue with white crest and red facial skin, but has

copious pale markings on underparts. Female generally chestnut brown with no crest; darker flight-feathers and especially tail. Immature mostly chestnut brown, with black markings on upperparts; pale fulvous throat, with rest of underparts chestnut brown vermiculated black; male assumes adult plumage in 1st year. Male of race *hatinhensis* differs from nominate only in having central pairs of rectrices white; female very similar to that of nominate *edwardsi*.

Habitat. Found in level or gently sloping terrain covered by secondary lowland evergreen forest with well developed understorey of palms and rattan, interspersed with patches of bamboo. Allegedly inhabits wet forest up to 600 m. Altitudes of collecting sites and observations during recent surveys suggest that species must occur, if it still survives, in forest on level ground rather than in hill forest. Race *hatinhensis* appears to be confined to forests of level lowlands in NC Annam; can apparently be found in dense vegetation along streams.

Food and Feeding. No information available.

Breeding. All information from captivity: clutch size 4-7; incubation 21-22 days; chicks have dark brown down above, chestnut on crown and sides, buff below.

Movements. No information available.

Status and Conservation. VULNERABLE. Mace-Land: *edwardsi* critical/extinct; *hatinhensis* endangered. CITES I. Only known from its very restricted range in small area of Vietnam. Recent fieldwork in historical range of nominate race failed to find species, and revealed area to be almost completely deforested; it may, however, still exist in small numbers (less than 1000 individuals); last specimen collected in 1928, but species reported to have been seen in 1985. Occurs in Annamese Lowlands Endemic Bird Area. Habitat destruction is clearly main cause for decline, but over-exploitation for food also undoubtedly important. Race *hatinhensis* recently found at Cat Bin; total surviving population now estimated to be within minimum and maximum limits of 100-10,000 individuals, based on available habitat and recent survey work; evidently declining. There are plans to expand recent surveys into Annamese lowland conservation project, led by BirdLife International. Taxonomic clarification required, as *hatinhensis* is known to survive, and may, or may not, be conspecific with *edwardsi*. Further surveys of potentially suitable areas are also urgently needed in S Thua Thien and Quang Tri Provinces, in order to determine presence of any suitable remaining forest patches, and whether they contain present species. A Population and Habitat Viability Assessment should be conducted to simulate the various consequences of different management options on prospects of species' survival, always assuming species remains extant. Large captive population of *edwardsi*, numbering over 500 birds this needs studbook management, especially in case *hatinhensis* really is a distinct species, and *edwardsi* is extinct in the wild.

Bibliography. Collar & Andrew (1988), Delacour (1949), Eames *et al.* (1992), Hachisaka (1941), King (1978/79), Letourneau (1993), Lovel (1977), Nguyen Cu & Eames (1993), Robson *et al.* (1989, 1993a, 1993b), Roles (1990), Rozendaal & Nguyen Cu (1991), Vo Quy (1975), Vuilleumier *et al.* (1992), Wildash (1968).

125. Swinhoe's Pheasant

Lophura swinhoi

French: Faisan de Swinhoe German: Swinhoe-fasan Spanish: Faisán de Swinhoe
Other common names: Formosan Pheasant

Taxonomy. *Euplocamus swinhoi* Gould, 1863, Taiwan.

Has also been placed in genus *Hierophasis*. Monotypic.

Distribution. Endemic to mountains of C Taiwan.

Descriptive notes. Male c. 79 cm (tail 41-50 cm); female c. 50 cm (tail 20-22 cm); (unsexed) c. 1100 g. Male mostly blackish blue, with glossy green feather-tinges on upperwing-coverts, chestnut-maroon patch on scapulars, and snowy white crest, upperback and central tail feathers; bright red wattles and facial skin. Female rather variable, but pale broad lanceolate markings diagnostic. Immature resembles female, but is duller and has upperwing-coverts spotted black and whitish; first-year male resembles adult male, but is duller, partly mottled brown and black, and has dark central rectrices; adult male plumage attained in 2nd year.

Habitat. Inhabits both primary and mature secondary hardwood forest, from 300 m up to 2000 m.

Food and Feeding. Very varied diet, including acorns, berries, flower buds, leaves and other plant materials; also earthworms, millipedes and termites and other insects. Specific items mentioned include berries of *Damianthus indicus* (Rubiaceae), and unspecified parts of *Polygonum chinense* (Polygonaceae), and probably *Neolitsea* (Lauraceae) and *Asplenium* (Polypodiaceae); a variety of other plant species and parts are reported to be consumed. Most feeding seems

to occur in early morning and late afternoon, typically along road edges in herbaceous ground cover; other areas of secondary growth are also used. Feeds by digging.

Breeding. Peak laying probably in Mar-May, unusually Feb, but some reports as late as Oct. Nest data scarce, but indicate that eggs are laid near foot of tree or under rocks, on bare earth or on a few fallen leaves. Clutch 4-8 eggs, local reports of 3-8 (2-12) unconfirmed; incubation in captivity 25 days, by female only; chicks have chocolate brown down above, whitish and rufous below, with orange rufous crown.

Movements. No information available.

Status and Conservation. VULNERABLE. Mace-Land: Safe. CITES I. Due to secretive nature of this, and other *Lophura* species, population estimates are difficult to make with any degree of confidence. Intensive fieldwork in early 1970's suggested that there might be 5000-10,000 individuals; species apparently common in suitable habitat, but declining. Known to have become extinct in several areas, including Kenting since 1960's, and Mits Kuan Tao and Chen Chung where last seen in late 1971; numbers much reduced in some other areas. Recent estimate of c. 6500 individuals in the Yushan National Park (64,229 ha); species also known from several other reserves and protected areas. Habitat is subject to variety of pressures, and species is also trapped for bird trade; in general, probably stable where protected, but declining elsewhere.

Bibliography. Cheng Tso-hun (1987), Collar & Andrew (1988), Delacour (1949), Dijkstra & Hue (1978), Hachisaka & Udagawa (1951), King (1978/79), Meyer de Schauensee (1984), Severinghaus (1977a, 1977b, 1978, 1980, 1986), Severinghaus & Blackshaw (1976), Severinghaus & Severinghaus (1990), Stokes & Williams (1971), Taka Tsukasa & Kano (1939), Tang Chan-zhu (1990), Zheng Guang-mei & Zhang Zheng-wang (1993).

126. Salvadori's Pheasant

Lophura inornata

French: Faisan de Salvadori German: Salvadorifasan Spanish: Faisán Sencillo
Other common names: Hoogerwerf's/Sumatran Pheasant (*hoogerwerfi*)

Taxonomy. *Acomus inornatus* Salvadori, 1879, Mount Singgalang, Padang, West Sumatra.

Has alternatively been placed either in genus *Chalcocornus* or in genus *Houppler*. Race *hoogerwerfi* sometimes considered a distinct species, but very poorly known, and male remains undescribed; might not even merit subspecific status. Two subspecies recognized.

Subspecies and Distribution.

L. i. hoogerwerfi (Chasen, 1939) - Aceh, N Sumatra.

L. i. inornata (Salvadori, 1879) - mountains of S Sumatra, S to Mt Dempo.

Descriptive notes. 46-55 cm; tail c. 16 cm. Male differs from other blackish pheasants by rather unspectacular plumage, pale eye-ring and pale greyish legs; crestless. Female has plumage characteristically covered with pale blotches and paler shaft streaks; pale eye-ring. Immature not described. Female of race *hoogerwerfi* differs from nominate female in having darker grey legs and more uniform, eventually unblotched plumage; male undescribed, although colour photographs (apparently of this form) suggest plumage similar to that of male of nominate *inornata*.

Habitat. Montane forest between 1000 m and 2200 m; recent record in somewhat degraded forest, although with undisturbed forest nearby. Race *hoogerwerfi* collected in forest at 600-2000 m; probable recent sightings on fairly dry forested slopes within same altitude range.

Food and Feeding. No information available.

Breeding. One nest of race *hoogerwerfi* containing 2 eggs found in Feb at 1800 m. No further information available from the wild. In captivity, a clutch of 2 eggs took 22 days to hatch.

Movements. No information available.

Status and Conservation. VULNERABLE. Mace-Land: *inornata* vulnerable; *hoogerwerfi* vulnerable. Nominative *inornata* definitely known from Mt Kerinci in W Sumatra and Mt Kaba in Bengkulu; no recent information from Mt Dempo in S. Until recently, not recorded in wild since period 1913-1917, when 34 specimens collected; rediscovered on Mt Kerinci in 1986, where has subsequently been resighted on a number of occasions; one pair observed on Mt Kaba in Apr 1989. Known to be present in one protected area, Kerinci Seblat National Park (15,000 km²), however, this park suffers heavy human pressure, with constant damage to habitat, which is evident in the very zone where the species has been located. Little recent information available, but total population reckoned perhaps to number less than 20,000 individuals; numbers may be stable at present in montane forest above current logging areas. No confirmed records of *hoogerwerfi* since the two females were collected in 1937 and 1939, although several recent sightings (apparently of this form) from Mantas Valley, in mountains of Aceh, this race appears to be confined to (ranging Leuser National Park (7927 km²)). Species, as a whole, considered vulnerable because of continued large-scale timber extraction, and also species' presumably small population size. Occurs in Sumatra and Peninsular Malaysia (above 800 m) Endemic Bird Area. No specific conservation actions are under way, extensive surveys required to establish limits of distribution, especially in protected areas, so that suitable habitat can be conserved effectively. Race *hoogerwerfi* requires particular attention, especially as might yet prove to be distinct species, and no definite records for over 50

years; possible recent records from Mamas Valley should be pursued. Species not protected by Indonesian law.

Bibliography. van Balen & Holmes (1993), Collar & Andrew (1988), Delacour (1949), Holmes (1989), Houpert & Lasière (1977), Lambert & Howes (1989), MacKinnon & Philipps (1993), van Marle & Voous (1988), Raethel (1988), Robinson & Kloss (1918, 1924), Roles (1990), Wells (1985).

127. Crestless Fireback

Lophura erythrophthalma

French: Faisan à queue rousse **German:** Gabelschwanzfasan **Spanish:** Faisán Colicanelo
Other common names: Rufous-tailed Fireback

Taxonomy. *Phasianus erythrophthalmus* Raffles, 1822, Bengkulu, western Sumatra. Has alternatively been placed in genus *Acomus* or genus *Houppifer*. Two subspecies recognized.

Subspecies and Distribution

L. e. erythrophthalma (Raffles, 1822) - Peninsular Malaysia and Sumatra.
L. e. pyronota (G. R. Gray, 1841) - N Borneo.

Descriptive notes. Male 47-50 cm (tail 15-18 cm), c. 1043 g; female 42-44 cm (tail 14-16 cm), one bird 837 g. Male distinctive, with bright ochraceous yellow central tail feathers; dark bluish black plumage, with greyish upperparts, and dark reddish rump; lacks crest of rather variable *L. ignita*. Female recalls male of *L. inornata*, but differs from all other blackish pheasants by lack of blue fringes on upperparts; has brownish head, greyish throat; also has spurs. Immature black, feathers with rufous chestnut tips; immature male assumes adult plumage at 4 months old. Male *pyronota* differs from nominate male by heavy pale

streaking on neck and underparts; uppertail-coverts steel blue.

Habitat. Found almost from sea-level up to c. 300 m in Malaysia, where may tolerate secondary forest; believed to be a lowland forest specialist in both Sumatra and Kalimantan. If tolerant of wetland forest conditions, range in Sumatra will be much larger, given extensive tracts of forest in E Sumatra, although these are rapidly disappearing.

Food and Feeding. Animal and plant material found in roughly equal proportions in gut contents; animal items included termites, ticks and grubs, plant matter consisted of small hard berries. One pair seen pecking at fallen fruits of *Kuena* (Myristicaceae). No further information available.

Breeding. Eggs found from mid-Mar to Jun. One nest of twigs was located between buttress roots of a dying tree. Clutch of 3-6 eggs; incubation 24 days; chicks have rich dark fulvous down.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Lande: *erythrophthalma* vulnerable (Malaysia), endangered (Sumatra); *pyronota* endangered. Sparsely distributed in Peninsular Malaysia, and presumably declining through loss of its lowland habitat. Estimated population, based on extent of available habitat, up to 20,000 individuals. Seems to occur at low densities in Sumatra and Kalimantan. Known to inhabit several protected areas: Krau Wildlife Reserve (530 km²), proposed Endau-Rompin State Park (total area c. 800 km², in states of Johore and Pahang) and in Taman Negara National Park (4343 km²) in Peninsular Malaysia; Gunung Mulu National Park (528 km²) in Sarawak; Way Kambas National Park (1300 km²), Sumatra; no records from existing protected areas in Kalimantan. Threatened by habitat degradation and loss to agriculture and clear-felling for timber production. Extensive surveys are needed in order to determine current distribution of species, and to assess its tolerance of habitat degradation, as well as to ascertain whether or not species occurs in wetland forest. CITES III in Malaysia.

Bibliography. van Balen & Holmes (1993), Banks (1935), Chasen (1939), Coomans de Ruiter (1946), Davison (1979a, 1980c), Davison & Scriven (1987), Delacour (1949), Dutton (1990), Gibson-Hill (1949), Holmes (1989), Holmes & Burton (1987), Jarvis & Medway (1968), MacKinnon & Philipps (1993), Mann (1987), van Marle & Voous (1988), Medway & Wells (1976), Robinson & Chasen (1936), Roles (1990), Siti Hawa Yatim (1993), Smythies (1957, 1981), Wells (1985, 1990).

128. Crested Fireback

Lophura ignita

French: Faisan noble **German:** Haubenfasan **Spanish:** Faisán Noble
Other common names: Vieillot's Fireback; Malaysian Fireback (*rufa*)

Taxonomy. *Phasianus ignitus* Shaw, 1797, Java; error = south Borneo (between Pontianak and Bandjarmasin).

Has alternatively been placed in genus *Euplocamus*. Race *rufa* has been considered a distinct species. Race *macartneyi* very variable, and perhaps an unstable form; might be hybrid of *rufa* and *ignita*; *macartneyi* is synonym of *macartneyi*. Four subspecies recognized.

Subspecies and Distribution

L. i. rufa (Raffles, 1822) - Malay Peninsula (S from Isthmus of Kra) and Sumatra (except SE).
L. i. macartneyi (Temminck, 1813) - SE Sumatra, from area of Palembang S to Lampung.
L. i. ignita (Shaw, 1797) - Kalimantan (Borneo) and Bangka I (off SE Sumatra).
L. i. nobilis (P. L. Sclater, 1863) - Sarawak and Sabah (N Borneo).

Descriptive notes. Male 65-70 cm (tail 24-30 cm), 1812-2605 g; female 56-57 cm (tail 15-19 cm), c. 1600 g. Both sexes unmistakable due to combination of characteristically shaped crest and blue facial skin. Immature resembles female, but has large black spots on upperwing-coverts; male darker than female, and assumes dull version of adult plumage at 4 months old. Races vary in size and especially in coloration of tail and underparts in male; race *nobilis* similar to nominate but larger; race *rufa* has crimson legs, and distinctive face wattles in male; males of race *macartneyi* very variable, with several apparently

co-existing colour morphs described, based mainly on amount of rufous on plumage; Bornean birds have yellowish central tail feathers.

Habitat. Probably restricted to plains and foothills in S Thailand, where upper altitude limit is not known. In Malaysia, sparsely distributed from near sea-level up to 1000 m or more, depending on locality. In Indonesia, found in Sumatra and Kalimantan, where regarded as lowland forest specialist; also recorded in logged and secondary forest, but not known from swamp forest.

Food and Feeding. No firm information, other than gut contents of leaves and seeds and some insects; species observed feeding on fallen figs.

Breeding. Little information available on breeding season, with an old record of eggs collected in Apr; also, 4 recently hatched chicks collected in Jul on Borneo. Clutch of 4-8 eggs; incubation 24 days (in captivity); chicks have blackish brown down above, buffy white and rufous below, with rufous crown.

Movements. No information available. Encounters are made unpredictably throughout suitable habitat; it is suggested that birds may be fairly mobile within a defined area, using different parts every few days.

Status and Conservation. VULNERABLE. Mace-Lande: Vulnerable. Population may total over 100,000 individuals but continuously declining; lowland forest habitat severely threatened in many areas. Rare in Thailand, where probably endangered as result of extensive destruction of lowland forests; now extinct on Phuket I. Probably only ever sparsely distributed in S Burma. Uncommon in Peninsular Malaysia; probably common in Sabah, where may actually be commoner in logged than in undisturbed forest. Apparently secure for the present in Indonesia; population of Bangka I, representing link between Sumatran and Bornean populations, is now probably endangered or even extinct, as result of habitat loss; reported to be common in dry, heavily disturbed forests of Way Kambas National Park, S Sumatra. Reported in Ulu Barito and near Malinau, E Kalimantan. Occurs in several protected areas: in Thailand, known from Khao Pra Bang Khrum; in Malaysia, from Taman Negara National Park (4343 km²), Krau Wildlife Reserve (530 km²), Gunung Mulu National Park (528 km²) and Danum Valley Research Centre; in Indonesia, from Way Kambas National Park (1300 km²) in Sumatra, and Tanjung Puting National Park (3050 km²) in Kalimantan. Threatened by habitat destruction for agriculture, and probably extirpated from areas where lowland forest has been lost; has been recorded from logged and secondary forest, but the limits of its tolerance to habitat alteration are not known; statements concerning effects of logging on species must be treated with caution at present because of methodological problems, e.g. small sample size; locally threatened by hunting. Distribution within protected areas should be more clearly established; monitoring of populations is required. CITES III in Malaysia. Not protected by Indonesian law.

Bibliography. van Balen & Holmes (1993), Chasen (1939), Collar & Andrew (1988), Coomans de Ruiter (1946), Davison (1980b, 1981c), Davison & Scriven (1987), Delacour (1949), Dutton (1990), Gibson-Hill (1949), Holmes (1989), Holmes & Burton (1987), Humphrey & Bain (1990), King *et al.* (1975), Lekagul & Round (1991), MacKinnon & Philipps (1993), Mann (1987), van Marle & Voous (1988), Medway & Wells (1976), Riley (1938), Robinson (1913), Robinson & Chasen (1936), Robinson & Kloss (1921, 1924), Roles (1990), Round (1988), Siti Hawa Yatim (1993), Smythies (1957, 1981, 1986), Wells (1985, 1990).

129. Siamese Fireback

Lophura diardi

French: Faisan prélat **German:** Prälatfasan **Spanish:** Faisán Siamese
Other common names: Diard's Fireback

Taxonomy. *Euplocamus diardi* Bonaparte, 1856, south Vietnam.

Has alternatively been placed in genus *Diardigallus*. Monotypic.

Distribution. E Burma through N, C & E Thailand, C & S Laos and N & C Kampuchea to C Vietnam.

Descriptive notes. Male c. 80 cm (tail 33-36 cm), one bird 1420 g; female c. 60 cm (tail 22-26 cm), 680-1025 g. Male distinctive, with mostly grey upperparts, large wattles and peculiar crest; long dark green tail, characteristic pattern on lower back and rump, and red legs are also distinctive features. Female too quite different from congeners, most notably in having upwringing and central tail feathers black with prominent buffy white barring. Immature similar to female, but duller; young male assumes adult plumage in 1st year, although plumage duller overall and tail shorter.

Habitat. A lowland forest resident. In Thailand, inhabits primary and secondary evergreen forest from plains up to c. 800 m. Also occurs in semi-evergreen and bamboo forest.

Food and Feeding. Believed to be omnivorous, feeding on a variety of fallen fruits and berries, and also insects, worms, small land-crabs, etc. Also claimed to forage by scratching in leaf litter, and searching for insects near cattle. No further information available.

Breeding. Little information other than eggs collected between mid-Apr and late Jun. One nest situated on ground in hollow at base of tree. Clutch seems to consist of 4-8 eggs; incubation 24-25 days (in captivity); downy chicks are mostly brown above, buffy white below.

Movements. No information available.

Status and Conservation. RARE. Mace-Lande: Vulnerable. Based on a recent population estimate for whole of Thailand of c. 5000 individuals, and amount of suitable habitat estimated to remain in other areas, overall population believed to amount to 5000-10,000 birds. Considered scarce in Southern Shan States, in E Burma, in late 1940's. Recently recorded, in Vietnam, at Buon Luo in C Annam; Son Tung in N Annam; and Kon Cha Rang, Gia Lai and Nam Bai Cat Tien National Park, Cochinchina; also, in Laos, at proposed protected area of Xe Pian; no recent information from Kampuchea. Nam Bai Cat Tien National Park (350 km²) in Vietnam, and Xe Pian proposed protected area in Laos are only known protected areas in which species occurs. Threatened by habitat degradation, and overexploitation for food and sport. As species is lowland forest specialist, it is very vulnerable to widespread habitat alterations; protection is a priority.

Bibliography. Anderson (1993), Baker (1928), Collar & Andrew (1988), Delignat (1945), Delacour (1949), Harrison (1968), Humphrey & Bain (1990), Lekagul & Round (1991), Nguyen Cu & Eames (1993), Riley (1938), Robson *et al.* (1989, 1993a, 1993b), Roles (1990), Round (1988), Smythies (1986).

130. Bulwer's Pheasant

Lophura bulweri

French: Faisan de Bulwer **German:** Bulwerfasan **Spanish:** Faisán Coliblanco
Other common names: (White-tailed) Wattled Pheasant

Taxonomy. *Lobiophasis Bulweri* Sharpe, 1874, Lawas Mountains, Sarawak.

Formerly placed in genus *Lobiophasis*. Monotypic.

Distribution. Inland Borneo. Recent record from Ulu Barito at 150-250 m extends previously known range S from main spinal ranges.

Descriptive notes. Male 77-80 cm (tail 45-46 cm), 1470-1800 g; female c. 55 cm (tail 17.5-19 cm), two birds 916 and 1004 g. Inconspicuous crimson eye-ring and blue facial skin distinctive. Male unmistakable, with voluminous white tail; plumage mostly bluish black with blue feather fringes, and glossy purple throat and breast; blue wattles can be distended to spectacular effect; red legs. Female is only crestless pheasant with blue facial skin. Immature similar to female, but has black marks and buff tips on upperwing-coverts; first-year male resembles adult male, but tail straight and dark chestnut instead of white.

Habitat. Recorded in sub-montane forest up to 1500 m in Kalimantan; in Sarawak and Sabah, mostly inhabits hill slopes in primary hill forest and montane forest between 300 m and 1500 m.

Food and Feeding. Omnivorous; judging by gut contents, ants and termites would seem to predominate; other food items recorded include small crickets, other Orthoptera, small seeds, etc. Scratches on forest floor for food.

Breeding. Indirect evidence suggests long season; immatures collected in Aug. implying egg-laying in Apr; courtship seen in Jul. Single nest known; discovered in Brunei in 1985, among buttress roots of tree in Nov; 1 egg clutch, female was flushed. Broods of 2 seen; clutch size elsewhere claimed to be 5 eggs. Incubation 24-25 days (in captivity).

Movements. No information available.

Status and Conservation. VULNERABLE. Mace-Landé: Vulnerable. Little reliable information, but based on anecdotal information and estimated range area, population may be in the order of 1000-10,000 individuals; possibly stable, but more likely to be declining due to loss and degradation of habitat; reported to be locally common in Malaysian Borneo (Sabah and Sarawak); in past, said to be very common in undisturbed areas of inland Borneo. Recorded from two protected areas: Bukit Raya Nature Reserve (up to 8000 km²) in Kalimantan; and Gunung Mulu National Park (528 km²) in Sarawak. Threatened by overexploitation for food, and loss and degradation of habitat. No specific conservation action undertaken to date; survey required in order to establish true status of species. Protected by Indonesian law.

Bibliography. van Balen & Holmes (1993), Banks (1935), Collar & Andrew (1988), Davison (1980c), Delacour (1949), Dutton (1990), Heinroth (1938), Holmes (1989), King (1978/79), Lambert (1993), MacKinnon & Philipps (1993), Mann (1987, 1989), Roles (1990), Schneider (1938), Smythies (1957, 1981), Wells (1985).

Genus *CROSSOPTILON* Hodgson, 1838

131. White Eared-pheasant

Crossoptilon crossoptilon

French: Hokki blanc **German:** Schmalschwan-/Ohrfasan **Spanish:** Faisán Orejudo Blanco
Other common names: Tibetan Eared-pheasant; Elwes's Eared-pheasant (*harmani*)

Taxonomy. *Phasianus crossoptilon* Hodgson, 1838, probably west China. Race *harmani* sometimes considered a distinct species. Intergrades among races reported, suggesting that several may be of dubious validity. Five subspecies currently recognized.
Subspecies and Distribution.
C. c. harmani Elwes, 1881 - SW & SC Tibet and extreme N Arunachal Pradesh (NE India).
C. c. drouyni J. Verreaux, 1868 - probably E Tibet.
C. c. dolani Meyer de Schauensee, 1938 - WC China (S Qinghai).
C. c. crossoptilon (Hodgson, 1838) - WC China (W Sichuan), SE Tibet and extreme NE India.
C. c. lichiangense Delacour, 1945 - SC China (NW Yunnan).

Descriptive notes. 86-96 cm; male 2350-2750 g, female 1400-2050 g; tail 46-58 cm. Unmistakable. Ear tufts shorter than those of other eared-pheasants. Female resembles male, but slightly smaller, darker and browner; lacks spurs. Immature greyer with buff, chestnut and dark brown markings above and below; acquires adult plumage after two months. Plumage pattern varies considerably between white and slaty grey races, but relation to geographical distribution is not clear.
Habitat. Subalpine coniferous forest between 3500 m and 3900 m, but down to 2800 m in winter.

Food and Feeding. Believed to feed on lily bulbs and stems and bulbs of wild onions; one crop in Dec was full of juniper berries; seen feeding on rowan/mountain ash (*Sorbus*). Feeds by pecking at leaves and digging.

Breeding. Little information from the wild. Eggs probably laid in May-Jun; two nests in late May, one in NE Assam (record questioned) at 3300-3600 m; one nest sited on ground in deep forest. Two clutches of 4 and 9 eggs; incubation (in captivity) 24 days, by female alone; chicks have chestnut brown and rufous down above, creamy yellow below.

Movements. In summer occurs in alpine meadows up to 4600 m, whereas in winter moves down to subalpine spruce and pine forest, possibly as low as 2800 m. Some birds, however, have been seen as high as 4500 m in winter.

Status and Conservation. VULNERABLE. Mace-Land: *harmani* endangered; *crossoptilon/dolani/drouyni/lichiangense* vulnerable. CITES I. Extensive range, but fragmented distribution and apparently specialized habitat requirements suggest that overall total may number as few as 20,000 birds; currently declining. Not known from any protected areas. Threatened by deforestation and hunting for food. Assessment of species' status in protected areas should be determined as soon as possible.

Bibliography. Ali & Ripley (1980), Allen, G.A. Jr. (1994), Cheng Tso-hin (1963, 1987), Collar & Andrew (1988), Delacour (1945), Deng Wei-jie (1990), Elchécopar & Hue (1978), Felix (1964), Gray (1958), Grunnt (1980), He Fen-qí & Cui Xie-zhen (1990), Jiang Zhi-hua (1979), King, B.F. & Peng Ji-tai (1991), King, W.B. (1978/79), Lamba (1980), Liu Ru-sun (1986a, 1986b), Liu Ru-sun *et al.* (1985), Lu Tai-chun (1986), Lu Tai-chun *et al.* (1989, 1990), Ludlow (1951), Ludlow & Kinnear (1944), Mallinson (1979), Robson (1986), Roles (1990), Schafer (1934), Tang Chan-zhu (1990), Vaurie (1965d, 1972), Zhang Zheng-wang (1989), Zheng Guang-mei & Zhang Zheng-wang (1993).

132. Brown Eared-pheasant

Crossoptilon mantchuricum

French: Hokki brun **German:** Brauner Ohrfasan **Spanish:** Faisán Orejudo Pardo
Other common names: Manchurian Eared-pheasant

Taxonomy. *Crossoptilon mantchuricum* Swinhoe, 1863, vicinity of Peking (Beijing); mountains beyond San-yu, Jilin. Monotypic.

Distribution. NE China. Now restricted to five widely separated areas, of which four are reserves; three in Shanxi and one in Hebei; one population recently found close to Beijing.

Descriptive notes. 96-100 cm; male 1650-2475 g, female 1450-2025 g; tail c. 54-5 cm. Unmistakable, as is only brownish *Crossoptilon*. Female usually slightly smaller, and lacks spurs. Immature mottled brown with buff feather tips and short tail; assumes adult plumage after 2 months.
Habitat. Montane broad-leaved and mixed coniferous forests between 1300 m and 2500 m.
Food and Feeding. Mostly plant matter; total of 62 plant, fungus and animal species recorded in diet; main food items include large-flower onion (*Allium macranthum*), sea-buckthorn (*Hippophae rhamnoides*), hawthorn (*Cacalia hastata*), oriental strawberry (*Fragaria orientalis*) and bird vetch (*Vicia cracca*). Seen in small groups digging around grass clumps and feeding on roots.

Breeding. Territories defended Apr-Jun. In Shanxi, 7 nests 210-360 m apart at 1800-2150 m, in larch (*Larix*) and spruce (*Picea*) forest. Nest is a shallow depression in ground. Clutch reportedly 4-14 eggs, and even 22 claimed; incubation (in captivity) 26-27 days, by female alone; downy chicks are mostly rufous and buff above, creamy white below.

Movements. Believed to undertake limited seasonal movements.

Status and Conservation. ENDANGERED. Mace-Land: Endangered. CITES I. Total population probably numbers 1000-5000 individuals, most occurring within protected areas in Shanxi and Hebei; perhaps stable. Occurs in Shanxi Mountains Endemic Bird Area. Small size of populations and their complete isolation from each other are major concerns. Populations outside protected areas probably prone to loss of habitat due to agricultural development and habitat degradation; some egg-collecting takes place. Survival of species is likely to depend upon continued protection of existing populations, and accumulation of sufficient information to permit successful management of small populations. A captive breeding programme is under way at the Pangquangou National Nature Reserve of the Brown Eared-pheasant.

Bibliography. Allen, G.A. Jr. (1994), Cheng Tso-hin (1963, 1987), Collar & Andrew (1988), Delacour (1945), Elchécopar & Hue (1978), Felix (1964), He Fen-qí & Lu Tai-chun (1991), Huang Shi-qiang & Li Fudai (1986b), King (1978/79), Lai Rong-xing (1986), Li Cheng-jie *et al.* (1984), Li Fu-lai & Huang Shi-qiang (1985a), Li Xiang-tao (1993), Liu Huan-jin & Lu Xin (1988), Liu Huan-jin & Su Hua-long (1987), Liu Huan-jin, Su Hua-long & Shen Shou-yi (1991), Liu Huan-jin, Su Hua-long *et al.* (1987), Liu Ru-sun (1986a, 1986b, 1986c), Liu Ru-sun *et al.* (1985), Lu Tai-chun & Lu Ru-sun (1983), Lu Tai-chun *et al.* (1990), Meyer de Schauensee (1984), Rank (1990), Ren Jian-qiang & Hu Yue (1990), Roles (1990), Su Hua-long *et al.* (1986), Tang Chan-zhu (1990), Thompson (1976), Vaurie (1965d), Wang Fu-lin *et al.* (1985), Wise & Fuller (1978), Zhang Jun *et al.* (1983), Zhang Xiu-xiang (1983), Zheng Guang-mei & Zhang Zheng-wang (1993).

133. Blue Eared-pheasant

Crossoptilon auritum

French: Hokki bleu **German:** Blauer Ohrfasan **Spanish:** Faisán Orejudo Azul
Other common names: Pallas's/Mongolian Eared-pheasant

Taxonomy. *Phasianus auritus* Pallas, 1811, interior of China; Sigu, Gansu. Monotypic.

Distribution. C & NC China from E Qinghai E through Gansu to Inner Mongolia, and S to W Sichuan.

Descriptive notes. c. 96 cm; male 1700-2110 g, female 1450-1880 g; tail 49-56 cm. Distinctive combination of grey rump and white base of several outer pairs of rectrices separates from congeners. Female usually slightly smaller and lacks spurs. Immature mottled dark grey-brown with buff feather tips and short tail; assumes adult plumage after 2 months.

Habitat. Coniferous and mixed forests, and among junipers and in scrub on alpine meadows above tree-line.

Food and Feeding. Predominantly vegetarian; takes buds and leaves of barberries, stems and roots of young grasses, and various

herb species; 9 stomachs contained 80% vegetable matter (spruce and *Polygonum* seeds, and leaves of various trees, sedges and herbs) and 20% beetles. Forages in small or large groups, digging during warmer months and feeding on leaf buds and similar during late autumn and winter.

Breeding. Season Apr-June. Nest is a slight depression, under cover of tree or scrub. Clutch averages 8 eggs (6-12); incubation (in captivity) 24-28 days, by female only; downy chicks like those of *C. mantchuricum*, but darker and greyer.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Land: Safe. Common throughout range, with no cause for concern. Little information on which to base population estimates, but surveys in Gansu, Sichuan and Qinghai suggest there may be hundreds of thousands of individuals; believed to be stable. Apparently occurs in many giant panda reserves, and so is well protected.

Bibliography. Allen, G.A. Jr. (1994), Cheng Tso-hin (1963, 1987), Delacour (1945), Elchécopar & Hue (1978), Felix (1964), Gray (1958), Li Chun-qu & Li De-huo (1981), Li Gui-yuan (1986), Liao Yan-fa (1984, 1985a, 1985b), Liao Yan-fa *et al.* (1984), Liu Ru-sun (1986a, 1986b), Liu Ru-sun *et al.* (1985), Lu Tai-chun *et al.* (1990), Meyer de Schauensee (1984), Tang Chan-zhu (1990), Thompson (1976), Vaurie (1965d), Zhang Yin-sun (1959), Zheng Guang-mei & Zhang Zheng-wang (1993), Zheng Sheng-wu & Liao Yan-fa (1983).

Genus *CATREUS* Cabanis, 1851

134. Cheer Pheasant

Catreus wallichii

French: Faisan de Wallich **German:** Schopffasan **Spanish:** Faisán Chir
Other common names: Chir/Wallich's Pheasant

Taxonomy. *Lophophorus (Phasianus) Wallichii* Hardwicke, 1827, Almora, India. Monotypic.

Distribution. Himalayas from extreme E Afghanistan and NE Pakistan to WC Nepal.

Descriptive notes. Male 90-112 cm (tail 45-58 cm), 1250-1800 g; female 61-76 cm (tail 32-47 cm), 900-1360 g. Not brightly coloured but nevertheless unmistakable. Very variable black markings on upperwing-coverts and on underparts, especially in male. Female considerably smaller. Immature like female but duller, less boldly marked and lacks crest.

Habitat. Occurs on steep grassy and craggy hillsides covered with scrub, stunted trees, and in secondary vegetation, from 1200 m up to 3050 m; in some areas, also found in burnt, felled and cut-over areas of mixed pine, juniper, fir and rhododendron forest with secondary growth.

Food and Feeding. Feeds on items such as roots, tubers, bulbs; buried seeds and possibly insect larvae and earthworms. A recent study found that all material in droppings was from plants; in Mar, mainly *Poa annua*, *Rosa moschata* and *Berberis* leaves; in Apr, *Rumex* roots, *Gnaphyllum*

hypoleuca leaves and *Arisaema jacquemonti* bulbs; in May, *Rumex* bulbs and buckwheat (*Phagopyrum tataricum*); and in Jun, *Frage-ria indica* leaves, buckwheat and *Poa annua*; no insect items found, but increased nitrogen excretion in Jun may come from this food source. Forages by digging.

Breeding. Breeds in late Apr-Jun, depending upon altitude. Monogamous. Calling at dawn and dusk throughout year, except in Jul-Sept, immediately after breeding period. Nest usually located in grass, at base of rocky crag. Usually 9-10 eggs (9-14); incubation (in captivity) 26 days, by female, although male stays

close by; chicks have grizzled chocolate brown down above, creamy white and greyish below.

Movements. During surveys and studies since 1980 species recorded from 1500 m up to 3140 m in India and Nepal, but detailed assessment of seasonal movements lacking; probably some altitudinal migration. At Dhorpatan, in Nepal, a site considered exceptionally high at over 2800 m, birds were recorded in late May and early Jun. Elsewhere reported from as low as 1200 m in cold weather, and up to 3000 m in summer.

Status and Conservation. ENDANGERED. Mace-Lande: Vulnerable. CITES I. Probably always occurred in very small, isolated populations; estimated density of 5-10 breeding females/km². Whilst species seems able to survive in such small numbers, each population is susceptible to a variety of pressures, which stem from requirement for a habitat that is heavily altered by man; its vocal nature makes it ready prey for hunters, and agricultural encroachment of hill grassland is also a threat. Repeat visits have been made to a number of sites surveyed several years previously and numbers appear to be stable. Occurs in at least 9 protected areas, including the Great Himalayan National Park in India and Lake Rara National Park in Nepal; population in Chail Wildlife Sanctuary, India, is probably the largest so far located; may be almost extinct in Pakistan. Future of species is likely to depend on effective ban of hunting, and appropriate management of grassland. **Bibliography.** Ali & Ripley (1980), Baker (1928, 1930), Beer & Cox (1980), Burt & Young (1988), Chaudhry (1993), Collar & Andrew (1988), Garson (1983), Garson *et al.* (1992), Gaston (1980a), Gaston & Singh (1980), Gaston, Garson & Hunter (1981a, 1981b, 1983), Gaston, Garson & Pandey (1993), Grahame (1988), Hussain (1990), Hussain *et al.* (1986), Inskipp (1991), Inskipp & Inskipp (1985, 1986), Kaul (1989, 1990a, 1990b, 1990c, 1993), King (1978/79), Lelliott (1981, 1987), Lelliott & Yonzon (1980a), Mirza (1980), Pandey (1993a), Qadri *et al.* (1990), Ridley & Islam (1987), Roberts (1991), Sathyakumar *et al.* (1992), Severinghaus *et al.* (1979), Sharma & Pandey (1989), Sharma *et al.* (1990), Young *et al.* (1987).

Genus SYRMATICUS Wagler, 1832

135. Elliot's Pheasant

Syrmaticus ellioti

French: Faisan d'Elliot German: Elliotfasan Spanish: Faisán de Elliot
Other common names: White-necked/Long-tailed Pheasant, (Chinese) Bar-backed Pheasant

Taxonomy. *Phasianus ellioti* Swinhoe, 1872, mountains near Ningpo, Zhejiang, China.

Has been placed in genus *Calophasis*. Monotypic.

Distribution. SE China from Jiangsu and Anhui S through Zhejiang, Fujian and Hunan to Guizhou and Guangxi.

Descriptive notes. Male c. 80 cm (tail 39-44 cm), 1044-1317 g; female c. 50 cm (tail 17-19.5 cm), 726-1090 g. Whitish grey (male) or fulvous grey (female) hood diagnostic. Female also differs from those of other *Syrmaticus* in black throat. Immature duller than female, with white throat; males show barred tail from early stage.

Habitat. Evergreen broad-leaved forest (*Lithocarpus*, *Cyclobalanopsis*, etc.) mixed evergreen broad-leaved and coniferous forest, and pure coniferous forest between 300 m and 1500 m.

Food and Feeding. Reported to feed on seed pods, seeds, berries and leaves of various

species; a few ants constitute the only animal material known.

Breeding. In W Zhejiang, laying from mid-Mar to late May. Display performed in early morning and early afternoon. Nest is simple; 24 cm long, 19 cm wide. Typically 5-8 eggs; incubation 25-26 days (in captivity); chicks have rufous chestnut down above, greyish white below, with rufous upper breast.

Movements. Believed to be sedentary.

Status and Conservation. ENDANGERED. Mace-Lande: Vulnerable. CITES I. Occurs in areas of SE China with dense human population. Whilst no good information available on abundance, species believed to survive in good numbers at some localities; total population size probably in tens of thousands; fragmented and declining. Known to occur in two natural reserves and possibly in several other small reserves; occurs in Fujian Mountains Endemic Bird Area. Deforestation already considered to have taken a considerable toll on species' habitat, and this continues, together with subsequent conversion of land to agriculture; additional pressure from hunting. Designation of more protected areas needed, and species should be monitored in these areas; reserves should be managed as network. **Bibliography.** Allen, G.A. III (1994), Cheng Tso-hin (1987), Collar & Andrew (1988), Ding Ping & Zhuang Yan (1988, 1989, 1990), Etchécopar & Hue (1978), He Fenshi & Lu (1991), King (1978/79), Knoder (1983), Li Bing-hua (1985), Long Di-zong (1985), Meyer de Schauensee (1984), Shen Jun & Yu Xin-hua (1988), Tang Chan-zhu (1990), Zheng Guang-mei & Zhang Zheng-wang (1993).

136. Hume's Pheasant

Syrmaticus humiae

French: Faisan de Hume German: Burmufasan Spanish: Faisán de Hume

Other common names: Mrs Hume's/Bar-tailed/Black-necked Bar-tailed Pheasant

Taxonomy. *Calophasis humiae* Hume, 1881, Manipur, north-eastern India.

Has been placed in genus *Calophasis*. Two subspecies recognized.

Subspecies and Distribution.

S. h. humiae (Hume, 1881) - mountains of extreme NE India E to R Irawaddy in Burma.

S. h. burmanicus (Oates, 1898) - CS China (SW Yunnan and Guangxi) and E Burma (E of R Irawaddy) SE to N Thailand.

Descriptive notes. Male c. 90 cm (tail 40-53.5 cm), 975-1080 g; female c. 60 cm (tail c. 20 cm), 650-850 g. Distinctive upperwing pattern and blackish blue neck diagnostic in combination. Female resembles that of *S. ellioti*, but paler and has pale fulvous brown throat; mantle feathers barred black with white centres. Immature like female but duller. Male of race *burmanicus* has steel blue of neck slightly more purplish and less extensive than nominate; rump whiter and tail paler.

Habitat. Inhabits open oak-pine forests with scattered clearings above c. 1200 m in Thailand.

Occurs between 1200 m and 2400 m in NE India

and Burma. In Guangxi (CS China), affects evergreen, broad-leaved and mixed forest at 740-1800 m. **Food and Feeding.** In China, race *burmanicus* recorded eating fruits, seeds, leaves, buds and roots of over 40 plant species, including *Pinus yunnanensis*, *Cunninghamia lanceolata*, *Cyclobalanopsis*, *Castanopsis delavayi*, oaks (*Quercus*) and wild mushrooms; some insects taken, but in breeding season plants comprise over 97% (dry weight) of stomach contents; those of young birds contained 50-90% insects (dry weight).

Breeding. Lays Mar; in Guangxi, pairing in early Mar. and mating seen in forest glades. Nests of dried leaves and *Pinus yunnanensis* twigs, liana strands and the bird's body feathers; nest is c. 25-30 cm in diameter. Clutch of 3-12 eggs; incubation 28 days, by female only.

Movements. Stated to move uphill to breed, but altitude limits in each season not reported.

Status and Conservation. RARE. Mace-Lande: *humiae* endangered; *burmanicus* vulnerable. CITES I. Total population estimated to be 1000-10,000 birds; declining. Based on anecdotal information and recent sight records, Thai population estimated to be in low hundreds. In China, 21 sites documented; presence confirmed at 2 sites in Thailand; little recent information from India and none from Burma. Found in Murlum and Blue Mountain National Parks in NE India; may occur in Doi Inthanon National Park in Thailand; not known to occur in any protected area in China. Threatened by habitat loss and degradation, including shortening rotation times of slash-and-burn agriculture in NE India; possibly overhunted for food. Extensive surveys required, especially in Thailand and NE India; further protected areas should also be designated.

Bibliography. Ali & Ripley (1980), Allen, G.A. III (1994), Baker (1928, 1930), Cheng Tso-hin (1987), Collar & Andrew (1988), Davison (1979b), Deignan (1945), Etchécopar & Hue (1978), Gaston (1980a), King (1978/79), Lamba (1980), Lekagul & Round (1991), Liu Xiao-hua *et al.* (1990), Meyer de Schauensee (1984), Round (1988), Sarker (1986), Smythies (1986), Tang Chan-zhu (1990), Zheng Guang-mei & Zhang Zheng-wang (1993).

137. Mikado Pheasant

Syrmaticus mikado

French: Faisan mikado German: Mikadofasan Spanish: Faisán Mikado

Taxonomy. *Calophasis mikado* Ogilvie-Grant, 1906, Mount Arizan, central Taiwan.

Has been placed in genus *Calophasis*. Monotypic.

Distribution. Mountains of C Taiwan.

Descriptive notes. Male c. 87.5 cm (tail 49-53 cm), c. 1300 g; female c. 53 cm (tail 17-22.5 cm), c. 1015 g. Male distinctive; white markings on upperwing- and uppertail-coverts variable; lower back and rump deep black, not bluish. Female resembles that of *S. humiae*, but is darker and more boldly marked with blackish and white. Immature similar to female but head, neck and throat spotted buffy white; in male, tail barred black and white at early stage.

Habitat. Forest with dense undergrowth of rhododendron and bamboo between 1600 m and 3300 m; also found in secondary habitats.

Food and Feeding. No information available.

Breeding. Little reliable information. Season uncertain but laying probably occurs from late Mar to mid-Jul. Nest apparently made of bamboo stalks on trunk or in branches of a fallen tree, c. 1 m off ground. In captivity: 5-10 eggs; incubation 28 days; chicks have pale chestnut, reddish and earthy brown down above, greyish white below.

Movements. No information available.

Status and Conservation. VULNERABLE. Mace-Lande: Safe. CITES I. Yushan National Park (640 km²) recently estimated to hold c. 10,000 individuals; species also known from several other reserves and protected areas. Less threatened by alteration of habitat than sympatric *L. swinhoii*, presumably because inhabits cold temperate forest at higher altitudes; like *L. swinhoii*, present species trapped for bird trade; numbers probably stable where species receives protection, but declining elsewhere. Occurs in Taiwan Island Endemic Bird Area.

Bibliography. Allen, G.A. III (1994), Bridgman (1993), Cheng Tso-hin (1987), Collar & Andrew (1988), Hachisaka & Udagawa (1951), King (1978/79), Poltack (1972), Rong Rong (1984), Sahin (1984), Severinghaus (1977a, 1977b, 1978, 1986), Severinghaus & Blackshaw (1976), Severinghaus & Severinghaus (1990), Tang Chan-zhu (1990), Zheng Guang-mei & Zhang Zheng-wang (1993).

138. Copper Pheasant

Syrmaticus soemmerringii

French: Faisan scintillant German: Kupferfasan Spanish: Faisán Cobreiro
Other common names: Soemmerring's Pheasant

Taxonomy. *Phasianus soemmerringii* Temminck, 1830, Japan (north Kyushu).

Has been placed in monotypic genus *Graphephasianus*. Intergrades between different races reported; races *intermedius* and *subrufus* may be synonymous with race *scintillans*. Hybridization with *Phasianus versicolor* occasionally recorded in the wild, the offspring being infertile. Five subspecies recognized.

Subspecies and Distribution.

- S. s. scintillans* (Gould, 1866) - N & C Honshu, Japan.
S. s. intermedius (Nagamichi Kuroda, 1919) - SW Honshu and Shikoku, Japan.
S. s. subrufus (Nagamichi Kuroda, 1919) - SE & SW Honshu and SW Shikoku, Japan.
S. s. soemmerringii (Temminck, 1830) - N & C Kyushu, Japan.
S. s. iijimae (Dresser, 1902) - SE Kyushu, Japan.

Descriptive notes. Male 87.5-136 cm (tail 48-98 cm); female of race *scintillans* 51-54 cm (tail 14-19 cm); one unsexed adult 907 g. Female resembles that of *S. humiae*, but has darker band on breast; to some extent intermediate between female of *S. humiae* and that of *S. ellioti*. Geographical variation appears to be clinal: males of southernmost races are darker and more richly coloured; much individual variation and some races may not be valid.

Habitat. Occurs in coniferous forest, especially of *Cryptomeria* and cypress, and in mixed forest with dense undergrowth; also in rough country in mountains, but always below 1500 m.

Food and Feeding. Diet consists of acorns and seeds of *Castanopsis*, *Machilus*, *Clevers*, *Castanea* and other forest trees; these are taken from forest floor. Many insect species and earthworms and small crabs also reported; diet of young birds consists mainly of animal matter.

Breeding. Little reliable information. Season from Mar in S. and Apr-May in N. Nest situated on ground, usually sheltered, for instance by a fallen tree. Normally 7 eggs (6-13); incubation 24-25 days (in captivity); chicks have chestnut down above, yellowish buff below.

Movements. No information other than that in N Honshu species is reported to descend to lower altitudes in winter.

Status and Conservation. Not globally threatened. Mace-Land: *soemmerringii*/*iijimae* insufficient information; *scintillans*/*intermedius*/*subrufus* insufficient information. No information available on status other than that at one time species was very common, and nearly 1,000,000 birds were shot each year; nowadays hard to find. There are no estimates of densities or population size, and distribution in protected areas is not documented. Overhunting for sport seems to be main reason for species' decline; if controlled, and birds and habitat are well managed, there seems to be potential for sustainable hunting for sport, "wise use", to play a role in conservation of species. As an island species, any potential threats from introduced predators should be assessed.

Bibliography. Allen, G.A. III (1994), Austin & Kuroda (1953), Brazil (1991), Delacour (1978), Hachisuka (1953), Kiyosu (1965), Kuroda (1926), Ogasawara (1969), Vaurie (1965d), Wayne (1969), Yamashina (1976).

139. Reeves's Pheasant

Syrmaticus reevesii

French: Faisan vénéré

German: Königsfasan

Spanish: Faisán Venerado

Other common names: Bar-tailed/White-crowned Long-tailed Pheasant

Taxonomy. *Phasianus reevesii* J. E. Gray, 1829, China. Monotypic.

Distribution. N & C China, locally from Inner Mongolia S through Shaanxi, Henan, Anhui and N Hubei to Sichuan; range much reduced.

Introduced to several areas, e.g. Britain (possibly extinct), France and Hawaii, but most of these populations are probably not self-sustaining; well established in Czech Republic.

Descriptive notes. Male c. 210 cm (tail 100-160 cm), c. 1529 g; female c. 75 cm (tail 36-45 cm), c. 949 g. Male unmistakable; breast varies from bright chestnut to black. Female has very distinctive head pattern; only female *Syrmaticus* without red bare skin around eyes; variable, sometimes paler than illustration. Immature similar to female but duller and paler.

Habitat. Inhabits woodland and areas of long grass between 200 m and 2600 m.

Food and Feeding. Legumes, acorns, seeds and buds, tubers, radishes and wild persimmons; some larval and adult insects also

taken. In Tuoda Forest, Guizhou, main food items include fruit and seeds of species such as oaks, *Pyracantha fortuneana*, *Rosa maisei* and *Cotoneaster dammeri*; also some insects. Food obtained by scratching ground and digging.

Breeding. In Tuoda Forest, from mid-Apr to mid-Jul. Nest is a shallow bowl lined with pine needles, leaves and herbs; typically on ground in grass or shrubs, in forest. Clutch of 6-9 eggs; incubation 24-25 days; downy chicks are mostly dark brown above, whitish buff below.

Movements. Believed to be fairly sedentary.

Status and Conservation. RARE Mace-Land: Endangered. Probably most threatened pheasant in China. Recent surveys suggest population of 5000; declining. Since mid-1980's, object of much survey and research effort by several Chinese ornithologists from Beijing Natural History Museum and Academia Sinica. Suffered from widespread deforestation in mountains of C China, and this continues; also from overexploitation for various purposes. Historical range has contracted by c. 50%, and species has been absent from N Qinling, Hebei and Shanxi for over 10 years; probably still occurs in Guizhou, NE Yunnan, Sichuan, Shaanxi, S Gansu, Hunan, Henan, Hubei and Anhui, but all populations small, with 20-50 birds recorded at many sites. Now known from four or possibly five reserves, some of which are very small. Largest population may be in Tuoda Forest Reserve of Reeves's Pheasant, created in May 1992 as a result of research and conservation efforts by Wu Zhi-kang. With so many populations comprising so few birds, regular, preferably annual, monitoring is very important, as is assessment of ecological requirements, so that effective management can be initiated. Establishment of network of protected areas is badly needed, combined with a public awareness programme which could use present species as flagship for habitat conservation. Tail feathers have long been used in head-dresses in traditional Peking Opera performances; a captive population in China could satisfy this culturally important market.

Bibliography. Allen, G.A. III (1994), Cheng Tso-hin (1963, 1987), Collar & Andrew (1988), Eichendorp & Hüc (1978), He Fen-qi & Lu (1991), Hu Xian-long & Wang Qi-shan (1981), Hsu Wei-shu (1989), King (1992), Knoder & Bailie (1956), Lever (1987), Meyer de Schauensee (1984), Tang Chan-zhu (1990), Vaurie (1965d), Wu Zhi-kang (1979b), Wu Zhi-kang & Hsu Wei-shu (1986), Wu Zhi-kang & Xu Wei-shu (1987), Wu Zhi-kang *et al.* (1993), Xu *et al.* (1990), Zheng Guang mei & Zhang Zheng-wang (1993).

PLATE 57

Family PHASIANIDAE (PHEASANTS AND PARTRIDGES) SPECIES ACCOUNTS

Genus *PHASIANUS* Linnaeus, 1758

140. Ring-necked Pheasant

Phasianus colchicus

French: Faisan de Colchide German: Fasan
Other common names: Common Pheasant

Spanish: Faisán Vulgar

Taxonomy. *Phasianus colchicus* Linnaeus, 1758, Africa, Asia = Rion River. Sometimes considered conspecific with *P. versicolor*, which is thus relegated to subspecies level; however, the two are not now generally regarded as conspecific, because present species, when introduced to Japan, is apparently unable to survive, presumably due to competition with *P. versicolor*, and failure to hybridize successfully; nevertheless, they hybridize extensively where both introduced in Hawaii. Internal taxonomy of species requires extensive revision. Populations of E-Asia sometimes considered to constitute a separate species, *P. torquatus*. Races currently accepted can be split into five or six groups, which may be a better guide to geographical variation. Thirty-one subspecies recognized.

Subspecies and Distribution.

P. c. septentrionalis Lorenz, 1888 - N Caucasus.
P. c. colchicus Linnaeus, 1758 - Transcaucasia, in E Georgia, NE Azerbaijan, S Armenia and NW Iran.
P. c. talischensis Lorenz, 1888 - SE Transcaucasia.
P. c. persicus Severtsov, 1875 - SW Transcaucasia.
P. c. bergii Zarudny, 1914 - islands of Aral Sea.
P. c. turkestanicus Lorenz, 1896 - Kazakhstan (valley of R Syrdar'ya).
P. c. mongolicus J. F. Brandt, 1844 - NE Russian Turkestan.
P. c. principalis P. L. Sclater, 1885 - S Russian Turkestan and N Afghanistan.
P. c. chrysomelas Severtsov, 1875 - Turkestan (upper R Amud ar'ya).
P. c. zerafschanicus Tamovskii, 1893 - S Uzbekistan (Bukhara, Zerafshan Valley).
P. c. zarudnyi Buturlin, 1904 - Turkestan (valleys of C Amud ar'ya).
P. c. bianchii Buturlin, 1904 - Turkestan (Amud ar'ya Delta).
P. c. shawii Elliot, 1870 - Chinese Turkestan.
P. c. tarimensis Pleske, 1888 - CE Chinese Turkestan.
P. c. hugenbecki Rothschild, 1901 - NW Mongolia.
P. c. edzinensis Sushkin, 1926 - SC Mongolia.
P. c. satscheuensis Pleske, 1892 - NC China (extreme W Gansu).
P. c. vlangalii Przevalski, 1876 - NC China (N Qinghai).
P. c. alaschanicus Alphéraky & Bianchi, 1908 - NC China (W foothills of Helan Shan).
P. c. sohokhotensis Buturlin, 1908 - NC China (Sohokhot Oasis in Helan Shan; possibly also this race in Qilian Shan).
P. c. pallasi Rothschild, 1903 - SE Siberia and NE China.
P. c. karpowi Buturlin, 1904 - NE China (S Manchuria and N Hebei) and Korea.
P. c. kiangsuenis Buturlin, 1904 - NE China (N Shanxi and Shaanxi) and SE Mongolia.
P. c. strachii Przevalski, 1876 - C China (S Shaanxi and S & C Gansu).
P. c. sueshanensis Bianchi, 1906 - WC China (NW Sichuan).
P. c. elegans Elliot, 1870 - WC China (W Sichuan).
P. c. decollatus Swinhoe, 1870 - C China (Sichuan E to W Hubei and S to NE Yunnan and Guizhou).
P. c. torquatus Gmelin, 1789 - E China (Shandong S to China-Vietnam border).
P. c. rothschildi La Touche, 1922 - SC China (E Yunnan) and N Vietnam.
P. c. takatsukasae Delacour, 1927 - S China (S Guangxi) and N Vietnam.
P. c. formosanus Elliot, 1870 - Taiwan.

Various races introduced into many different countries, especially in Europe, North America, Australia (unsuccessfully), Tasmania and New Zealand.

Descriptive notes. Male 75-89 cm (tail 42.5-59 cm), 770-1990 g; female 53-62 cm (tail 29-31 cm), 545-1453 g; wingspan 70-90 cm. Male highly variable according to race, but usually not as dark as male *P. versicolor*; has longer tail, and at least some coppery colouring on underparts. Female differs from that of *P. versicolor* in paler, less blotched and vermiculated plumage. Immature resembles female, but duller and has shorter tail. Considerable geographical variation in many aspects of male plumage, partly clinal, partly not; white ring on neck usually absent in W, present in most of E races. Five subspecies

groups normally identified on basis of male plumage; white wing-coverts distinguish both *mongolicus* group (with more coppery upperparts), and *chrysomelas/principalis* group (with a more orange or yellowish tinge on upperparts); brown or buff wing-coverts distinguish *colchicus* group (with reddish brown rump), *tarimensis* (with yellowish cast on green rump), and *torquatus* group (with greyish or bluish cast on green rump); within each group, species differ in colour of head and neck gloss, and in other details of plumage.

Habitat. Considerable variation in habitat throughout natural range. Mainly overgrown edges of rivers, hilly areas close to cultivation and flat land under cultivation.

Food and Feeding. In natural range, diet consists primarily of plant matter, with much less animal food: fruits, seeds, leaves, buds and insects in autumn; fresh buds, grasses, leaves, insects and small invertebrates in spring; birds seen flying into grain fields to feed. Where introduced, a very diverse diet has been described, depending on local and seasonal food availability, indicating opportunism and omnivorous tendency; prefers large, energy-rich kinds of food, e.g. cultivated grains, mast and fruits.

Breeding. Season believed to be highly variable throughout both native and introduced ranges. In Jiangsu, CW China, harems of 3-5 females form from mid-Feb; in Azerbaijan, laying in Apr-May. Nest is a shallow depression in ground, lined with plant material from vicinity of nest, or unlined; clutch of 9-14 eggs; incubation 22 days. Where introduced, and more studied: normally 7-14 eggs (1-28); incubation 23-25 days; chicks have cinnamon and buff down above, with central broad black streak, pale creamy buff below.

Movements. Only information from native range is of several mass-migrations, mainly involving adult males moving from China into Amur Basin, E Russia, in severe winters. In introduced range, sedentary, although birds may move locally to feed on more open habitats during non-breeding season.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Only one reliable density estimate from any part of native range: at Panguangou National Nature Reserve in 1989, an estimated autumn density of 64 birds/km², a density similar to that found on managed estates in Britain. Other reports state that it is commonest game bird in China, given its wide distribution and tolerance of a wide variety of habitats; possibly tens of millions of birds in the wild; declining in some areas, but stable at most sites. Extensively hunted, both for food and sport, and suffering from agricultural intensification in some areas, but still widely distributed outside protected areas. Population declining in Taiwan, fairly common in E and S, but scarce in NW, disappeared from some lowland areas which have been lost to development. In late 1940's was common in NE Burma, but no recent data. Very little information available about status in W part of natural range. In Azerbaijan, nominate *colchicus* is common resident, with population of c. 20,000-25,000 individuals; race *tarimensis* is very rare resident, with only c. 200-300 individuals, following decline due to habitat loss and uncontrolled hunting, which together have brought it to brink of extinction, in 1940's and 1950's, estimated c. 40,000 birds killed by hunters each year. Common to superabundant in many parts of introduced range, where wild populations frequently bolstered by large numbers of captive-bred birds for shooting.

141. Green Pheasant

Phasianus versicolor

French: Faisan versicolore

German: Buntfasan

Spanish: Faisán Verde

Other common names: Japanese Pheasant

Taxonomy. *Phasianus versicolor* Vieillot, 1825. Java; error = Japan.

May be conspecific with *P. colchicus*, but in Japan the latter apparently dies out when introduced in range of present species, as seems unable to hybridize successfully; nevertheless, they hybridize extensively, where both introduced in Hawaii. Hybridization with *Symnaticus soemmerringii* occasionally recorded in the wild. Three subspecies recognized.

Subspecies and Distribution.

P. v. versicolor Vieillot, 1825 - SW Honshu and Kyushu, Japan.

P. v. tanensis Nagamichi Kuroda, 1919 - EC Honshu (Izu and Miura Peninsulas) and nearby Izu Is. and Tanegashima and Yakushima (off S Kyushu), Japan.

P. v. robustipes Nagamichi Kuroda, 1919 - Sado and most of Honshu, Japan.

Introduced to Hawaii.

Descriptive notes. Male c. 81.5 cm (tail 27-42.5 cm), 900-1400 g; female c. 58 cm (tail 21-27.5 cm), 692-970 g. Male differs from that of *P. colchicus* by shorter tail and usually much darker plumage, all dark green below; a grey morph is said to exist. Female differs from that of *P. colchicus* by more blotched and vermiculated underparts, blacker and more contrasted markings on mantle, and shorter tail. Immature similar to adult female. Races vary slightly in general colour tone of male's plumage, and in intensity of scaling on breast feathers.

Habitat. Occurs in park and farmland, areas of bush and open woods on plains and in relatively low hills, up to c. 1000 m; nests from sea-level up to 900 m.

Food and Feeding. Diet believed to be similar to that of *P. colchicus*, but possibly with higher proportion of wild seeds, fruits, berries and nuts, and fewer cultivated grains. Fruits identified include those of *Rosa*, *Elaeagnus*, *Viburnum*, *Viscum* and *Diospyros*; mast includes acorns, chestnuts and seeds of Japanese magnolias.

Breeding. Probably Apr-May in C Japan. Nest placed in cover on ground, usually close to low bushes or at base of tree. Clutch of 6-12 eggs (up to 15); incubation 23-25 days; downy chicks are strongly marked, and generally similar to those of *P. colchicus*.

Movements. Only information is of some seasonal movements in high snowfall areas of N Honshu. Apparently performs daily movements associated with feeding.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Declared Japan's national bird in 1947; familiar to people in legends, and prized by hunters. No density estimates available, but in early 1980's it was reported that over 100,000 captive-reared birds were released each year, and that annual bag was of over 500,000 birds. Shooting of females is prohibited; numbers of males killed has not dropped, unlike the case of *S. soemmerringii*.

Genus CHRYSOLOPHUS J. E. Gray, 1834

142. Golden Pheasant

Chrysolophus pictus

French: Faisan doré

German: Goldfasan

Spanish: Faisán Dorado

Taxonomy. *Phasianus pictus* Linnaeus, 1758. China.

Monotypic.

Distribution. C China, from SE Qinghai and S Gansu E through S Shaanxi to W Henan and W Hubei, and S through Sichuan and Guizhou to N Guangxi.

Introduced very locally to England.

Descriptive notes. Male 100-115 cm (tail 63-79 cm), 575-875 g; female 61-70 cm (tail 34-37.5 cm), 550-700 g; wingspan 65-75 cm. Male unmistakable. Female differs from that of *C. amherstiae* by velvety legs and ornate skin, more golden tone to plumage, and more pointed tail feathers. Immature like female but paler and less distinctly barred.

Habitat. Inhabits mountains and valleys with thick undergrowth of shrubs and bamboo.

Food and Feeding. Diet consists primarily of leaves and tender shoots of shrubs, leaves and shoots of bamboo, and rhododendron flowers; also some spiders and various insects taken.

Breeding. Little known. Believed to start breeding in early Apr; one clutch apparently found in bamboo grove with tall herbs and rocky outcrops, lays 5-11 eggs (introduced populations incubation 22 days; chicks have fulvous brown down above, with pale buff bands, buffy white below, but somewhat yellower than those of *C. amherstiae*).

Movements. Seasonal movements are probably fairly limited.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Population estimated in hundreds of thousands at many sites, but declining. Timber extraction, capture for live bird trade, and overexploitation for food are all contributing to drop in numbers; considered an expensive delicacy in restaurants. Known from several protected areas where hunting and deforestation are prevented.

Bibliography. Baker (1965), Cheng Tso-hin (1963, 1987), Cramp & Simmons (1980), Deng Wei-jie (1990), Eichécopar & Hùe (1978), He Fen-qí & Cui Xie-zhen (1990), Hu Tie-qing *et al.* (1988), Lever

(1987), Li Fu-lai & Huang Shi-qiang (1985b), Li Xiang-tao (1988), Meyer de Schauensee (1984), Pang Bing-zhang (1964, 1990), Tang Chan-zhu (1990), Vaurie (1965d), Wen Xian-ji & Yang Lan (1990), Wu Zhi-kang (1980), Zhao Xuan (1956), Zheng Guang-mei & Zhang Zheng-wang (1993).

143. Lady Amherst's Pheasant

Chrysolophus amherstiae

French: Faisan de Lady Amherst **German:** Diamantfasan **Spanish:** Faisán de Lady Amherst

Taxonomy. *Phasianus Amherstiae* Leadbeater, 1829. Mountains of CochinChina; error = Yunnan. Monotypic.

Distribution. NE Burma, extreme SE Tibet and SW China (from W Sichuan S to Yunnan and W Guizhou).

Introduced very locally to British Is.

Descriptive notes. Male 130-173 cm (tail 83-115 cm), 675-850 g; female 66-68 cm (tail 28-37 cm), 624-804 g; wingspan 70-85 cm. Male unmistakable. Female differs from that of *C. pictus* by

bluish grey legs and orbital skin, richer rufous tone to plumage, and more rounded tail feathers. Immature similar to female but paler and less distinctly barred.

Habitat. Inhabits wooded hills and bamboo, dense shrub patches and thickets; occurs between 2100 m and 3600 m, usually at higher altitudes than *C. pictus*.

Food and Feeding. Two crops contained many earwigs of various species, spiders, small beetles and fern fronds; also bamboo sprouts, which appear to be a preferred food item. Chicks recorded feeding on fruits of *Rubus*, *Coria sinica* and *Vaccinium spregelii*.

Breeding. Data from C Yunnan (S China). Lays from mid-Apr; males territorial in evergreen coniferous and secondary pine (*Pinus armandi*) forest from mid-Mar. Nest is round and shallow, lined with dead leaves, and situated under thicket or dead branches. Four nests contained 6 eggs, one contained 7 eggs; incubation 24 days, by female only; chicks have fulvous brown down above, with pale buff bands, buffy white below.

Movements. Probably performs substantial altitudinal movements, given high altitudes at which occurs in summer. Reported from foothills during severe weather.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Based on intensive field-work in China and surveys elsewhere, total population estimated in tens of thousands. Not common along Ngawchang Valley, NE Burma, in late 1940's. Habitat believed to be suffering from variety of pressures and becoming increasingly fragmented; species is also subject to overexploitation for food.

Bibliography. Baker (1930, 1965), Bland & Han (1993), Cheng Tso-hin (1963, 1987), Cramp & Simmons (1980), Eichécopar & Hùe (1978), Han Lian-xian *et al.* (1988, 1989, 1990), He Fen-qí *et al.* (1990), He Fen-qí & Cui Xie-zhen (1990), King, B.F. Genus *POLYPLECTRON*

Temminck, 1813

144. Bronze-tailed Peacock-pheasant

Polyplectron chalcurum

French: Éperonnier à queue bronzée Spanish: Espolonero Colibronceado
German: Bronzeschwanzfasan
Other common names: Sumatran/Lesson's Peacock-pheasant

Taxonomy. *Polyplectron chalcurum* Lesson, 1831, Java; error = Bengkulu, west Sumatra. Formerly placed in genus *Chalcus* together with *P. inopinatum*. Validity of race *scutellatum* has been questioned, as differences are slight and are masked by considerable variation between individuals. Two subspecies recognized.

Subspecies and Distribution.

P. c. scutellatum Chasen & Hoogerwerf, 1941 - mountains of N Sumatra.
P. c. chalcurum Lesson, 1831 - mountains of S Sumatra.

Descriptive notes. Male c. 56 cm (tail 26-38 cm), 370-590 g; female c. 40 cm (tail 18-22 cm), 238-269 g. Only member of genus in which both sexes have no ocelli at all; instead, tail has metallic purplish violet patches near the tip. Female similar to male, but considerably smaller, with much shorter tail. Immature resembles adult, but slightly paler and redder, with less bluish purple on tail; in first-year male the iridescent patches may reach tail tip. Race *scutellatum* said to be more strongly marked above than *chalcurum*, although this may be confounded by extensive individual variation.

Habitat. Inhabits variety of lower montane forest habitats, including both undisturbed and logged forest; also recorded in small remnant patch of forest; occurs between 800 m and 1700 m throughout mountains of Sumatra.

Food and Feeding. Several crops contained small fruits and insects. No further information available.

Breeding. No information from the wild. In captivity: clutch of 2 eggs; incubation 22 days; chicks have blackish brown down above, brownish buff below.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Land: Vulnerable. Recent records at several sites in N & C Sumatra, from Ketambe (Gunung Leuser) S to Mt Kerinci; fairly common in places, e.g. Padang Highlands. Found in montane forests, which are still widespread and fairly secure. Based on anecdotal information and available habitat, population is estimated to number tens of thousands; thought to be declining in some areas, e.g. Brestagi, due to hunting and trapping, but overall regarded as probably safe in short term, mainly because occupies mountainous terrain, and also because seems to tolerate certain degree of disturbance to habitat. Occurs in both Kerinci-Seblat National Park (15,000 km²) and Gunung Leuser National Park (7927 km²), with several fairly recent reports from both. Up to 50% of what is believed to be suitable habitat is already covered by some form of protection status. Species has restricted range, occurring in Sumatra and Peninsular Malaysia (above 600 m) Endemic Bird Area. Habitat degradation and loss, and in places overexploitation are main threats. Not protected by Indonesian law.

Bibliography. Andrew (1992), van Balen & Holmes (1993), Davison (1985a, 1985c, 1986c), Holmes (1989), MacKinnon & Philipps (1993), van Marle & Voous (1988), McGowan (1992a), Robinson & Kloss (1918, 1924), Roles (1990), Searle (1986, 1989), Wells (1985).

145. Mountain Peacock-pheasant

Polyplectron inopinatum

French: Éperonnier de Rothschild Spanish: Espolonero de Rothschild
German: Rothschildpfaufasan
Other common names: Rothschild's/Mirror/Malayan Peacock-pheasant

Taxonomy. *Chalcus inopinatus* Rothschild, 1903, Ulu Pahang, Peninsular Malaysia.

Formerly placed in genus *Chalcus* together with *P. chalcurum*. Monotypic.

Distribution. Mountains of Main Range, Peninsular Malaysia.

Descriptive notes. Male c. 65 cm (tail 32-40 cm); female c. 46 cm (tail 22-27.5 cm). Characteristic contrast between mainly chestnut mantle, wings and back, and greyish black underparts and head. Male has very small blue ocelli (with a white spot at the base of each ocellus) on mantle and wings. Female resembles male but considerably smaller, with shorter tail; ocelli on upperparts replaced by black spots. Immature similar to adult female, but male is longer-legged.

Habitat. Occurs throughout unlogged upper dipterocarp forest, and both lower montane and upper montane forest, from 900 m up to 2000 m.

Food and Feeding. One crop contained spiders, white ants, several grubs and other unidentified animal material; also reports of birds having consumed other invertebrates and fruits of rattan *Calamus*. No further information available.

Breeding. Very little information from the wild: an old nest found at altitude of 970 m, placed among rocks between two fallen trees; small chick collected in late Feb. In captivity: clutch of 2 eggs; incubation 19-21 days; chicks have rufous down above, buff below.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Land: Vulnerable. Based on anecdotal information and extent of habitat available, population is estimated to be in the thousands, and probably stable or declining slightly. Present in Fraser's Hill (30 km²) and Cameron Highlands (649 km²) Wildlife Sanctuaries, Krau Wildlife Reserve (530 km²) and Taman Negara National Park (4343 km²). Species has restricted range, occurring in Sumatra and Peninsular Malaysia (above 600 m) Endemic Bird Area. Threatened by habitat destruction for agriculture and possibly also by urban development. Major threat is the possibility of a road linking the hill stations of Genting Highlands, Fraser's Hill and Cameron Highlands, which would destroy much montane forest along Main Range. An international studbook and breeding consortium was initiated during 1992 and is co-ordinated by New York Zoological Society/Wildlife Conservation International and Department of Wildlife and National Parks, Peninsular Malaysia: the captive population comprised 111 individuals in Feb 1993. CITES III in Malaysia.

Bibliography. Benning & Sui Hwa Yatim (1992), Davison (1985a, 1986c, 1992), Davison & Searle (1987), Denham (1978), Gibson-Hill (1949), McGowan (1992a) Medway & Wells (1976), Roles (1990), Searle (1986, 1989), Sui Hwa Yatim (1993), Welk (1985, 1990).

146. Germain's Peacock-pheasant

Polyplectron germaini

French: Éperonnier de Germain Spanish: Espolonero de Germain
German: Brauner Pfauasan

Taxonomy. *Polyplectron germaini* Elliot, 1866, Cochinchina.

Sometimes considered to form a superspecies with *P. bicalcaratum*. Monotypic.

Distribution. S Vietnam N to 14° N, in SC Annam. Reports claiming that species also occurs in Kampuchea and Thailand are disputed.

Descriptive notes. Male c. 56 cm (tail 25-32 cm), one bird 510 g; female c. 48 cm (tail 22-25 cm), one bird 397 g. Male differs from those of other *Polyplectron* with large ocelli on upperparts by lack of crest or ruff, the ocelli on the mantle and wings are surrounded by a pale, golden brown ring. Female smaller and slightly duller; the blue ocelli on the mantle and wings are somewhat triangular, while the green ocelli on the tail lack the pale border. Immature similar to adult female, but has ocelli blackish.

Habitat. Found in lowland and sub-montane forests; also seen in thorny bamboo brakes. Appears to tolerate a certain degree of habitat disturbance, and has been recorded in both logged and secondary forest.

Food and Feeding. No information available.

Breeding. No reliable information available from the wild. In captivity: clutch of 1-2 eggs; incubation 21 days; chicks have dark chestnut brown down on upperparts, more buff-coloured on underparts.

Movements. No information available.

Status and Conservation. RARE. Mace-Land: Vulnerable. CITES II. Very little recent information available; heard daily in Nam Bai Cat Tien National Park (350 km²) during surveys in early Jan 1990; appears to tolerate some habitat disturbance. Anecdotal information suggests a wild population of less than 10,000 individuals, which is probably declining. Species has restricted range, occurring in Cochinchina Endemic Bird Area. Threatened by overexploitation for food, and also by habitat destruction for agriculture. More information is required on degree of security afforded by protected areas.

Bibliography. Anderson (1993), Collar & Andrew (1988), Davison (1985a, 1986c), Eames *et al.* (1992), Hing (1985), Lowe (1925), McGowan (1992a), Nguyen Cu & Eames (1993), Riley (1938), Robson *et al.* (1993, 1993b), Roles (1990), Searle (1986, 1989), Wayne (1969), Wildash (1968).

147. Grey Peacock-pheasant

Polyplectron bicalcaratum

French: Éperonnier chinquois German: Grauer Pfauasan Spanish: Espolonero Chinquois
Other common names: Iris/Chinquois Peacock-pheasant

Taxonomy. *Pavo bicalcaratus* Linnaeus, 1758, China; error = Thoungyah, Burma.

Sometimes considered to form a superspecies with *P. germaini*. Five subspecies recognized.

Subspecies and Distribution.

P. b. bakeri Lowe, 1925 - hills of NE India and Bhutan, from Sikkim E to Manipur, and maybe on into Burma.

P. b. baileyi Lowe, 1925 - unknown; thought to occur in W Assam or E Himalayas.

P. b. bicalcaratum (Linnaeus, 1758) - W & S Burma E through CS China (W Yunnan) to NW Vietnam and SE to SW Thailand (N of Isthmus of Kra).

P. b. ghigii Delacour & Jabouille, 1924 - N & C Vietnam and C Laos.

P. b. katusmatiae Rothschild, 1906 - Hainan I (S China).

Descriptive notes. Male 56-76 cm (*bicalcaratum*, *bakeri*); c. 53 cm (*katusmatiae*), tail 35-40 cm (*bakeri*), 28-30 cm (*katusmatiae*); 568-910 g (*bakeri*). Female 48-55 cm (*bicalcaratum*, *bakeri*), c. 40 cm (*katusmatiae*), tail 23-25.5 cm (*bakeri*), 17-19 cm (*katusmatiae*); c. 400 g (*katusmatiae*). Male has a full crest that wings spread, dips forward over neck, crest of ocelli on mantle and wings is surrounded by a white ring. Female resembles male, but smaller, with shorter crest; plumage generally darker and duller, and ocelli small and blackish, with white reflections. Immature similar to adult female, but male has longer legs. Races differ in general coloration of male, greyer in W, browner in E, and in size; easternmost race *katusmatiae* is smallest.

Habitat. Inhabits dense evergreen and semi-evergreen forest up to 1300 m, up to 1800 m in Thailand. Race *katsumatae*, at least, can survive in secondary habitats, but probably only in mature secondary forest.

Food and Feeding. Diet apparently consists of berries, fruits (plums and *Zizyphus* identified), seeds, wild figs, grubs, ants, other insects, snails and other small animals; particularly favours termites; bamboo seeds eaten when available. As are rice and grain from village cultivation. Foraging slow and secretive, birds scratching for food in quiet manner.

Breeding. In NE India. Mar-Jun, mainly Apr-May; in Bangladesh, Apr-May. Nest located in a hollow, usually at base of bamboo clump or in thick bushes; tangles of secondary vegetation apparently favoured. Clutch probably consists of 2 eggs, but reliable data lacking; incubation 21 days (in captivity); chicks have dark brown down above, tawny buff below.

Movements. No information available.

Status and Conservation. Not globally threatened. Mace-Lande: *bicalcaratum/bakeri/bailiyilghigii* safe; *katsumatae* endangered. CITES II. Very little firm information available from NE India and Bhutan, but species probably present in protected tropical forest in NE India; suitable habitat still likely to exist in Bhutan; rare breeding resident in Bangladesh. In China believed to be very rare and declining overall; extent of range is decreasing in Hainan, but possibly expanding in Yunnan. In Thailand, widely distributed and fairly common in best protected and largest areas; population estimate in thousands; may be stable or slightly declining. No recent information from Burma or Laos, but formerly considered very common in N Burma and Tenasserim and common everywhere else in suitable habitat, except for Pegu Yomas. Recently reported from several sites in Vietnam, including Bach Ma National Park. Main pressures are those to habitat, although overhunting is also a problem. Hainan race, *katsumatae*, is considered worthy of special conservation attention because of morphological differences with the continental races, and geographical isolation from them; known from three natural reserves in Hainan, but their effectiveness in terms of protecting species is uncertain; at least one, Ba Wang Ling (20 km²) is probably not effective.

Bibliography. Ali & Ripley (1980), Anderson (1993), Baker (1928, 1930, 1935), Cheng Tso-hin (1987), Davison (1985a, 1986c), Deignan (1945), Eichéopar & Hue (1978), Flieg (1973), Gao Yu-ren (1991), Humphrey & Bain (1990), Inskipp & Inskipp (1993b), Kaul & Ahmed (1993), Lamba (1980), Lekagul & Round (1991), Lowe (1925), McGowan (1992a), Meyer de Schauensee (1984), Mukhim & Michael (1993), Nguyen Cu & Eames (1993), Pocock (1911), Robinson & Kloss (1921), Robson *et al.* (1989, 1993a, 1993b), Roles (1990), Sarker (1986), Searle (1986, 1989), Smythies (1986), Stapel (1976), Tang Chan-zhu (1990), Zheng Guang-mei & Zhang Zheng-wang (1993).

148. Malaysian Peacock-pheasant

Polyplectron malacense

French: Éperonnier malais German: Malaienpfaufasan Spanish: Espolonero Malayo
Other common names: Malay(an)/Crested Peacock-pheasant

Taxonomy. *Pavo malacensis* Scopoli, 1786, East Indies = Malacca.

Forms superspecies with *P. schleiermacheri* and possibly *P. emphanum*. *P. schleiermacheri* has been considered race of present species. Monotypic.

Distribution. Malay Peninsula (almost exclusively S of Isthmus of Kra) in extreme S Burma, S Thailand and Peninsular Malaysia. Possibly extinct in Thailand. Sumatra has traditionally been included in species' distribution, but there is no evidence to support this claim.

Descriptive notes. Male c. 50 cm (tail 24-25 cm); female c. 40 cm (tail 18-19 cm); c. 586-680 g. Male has long crest of disintegrated feathers; each ocellus on the mantle and wings is surrounded by buff; tail proportionately much shorter than in *P. bicalcaratum*. Female has much shorter crest, and ocelli on mantle and upperwing-coverts replaced by triangular black spots. Immature similar to female, with black spots on wings.

Habitat. Occurs in evergreen rain forest in level lowlands. Inhabits forest dominated by tall dipterocarp trees on flat or gently undulating ground. Upper altitude limit appears to be c. 150 m, but birds may exceptionally be found up to 300 m. Has been recorded in secondary forest, but tolerance of habitat alteration is probably limited.

Food and Feeding. Diet largely unknown, but species is probably opportunistically insectivorous, frugivorous, or both. Faeces and stomach contents include invertebrate and plant material: parts of anthropod and grasshopper, ants (*Camponotus*) and Diptera; also fruits (Fagaceae; *Lithocarpus*, Annonaceae and Leguminosae), moss, twigs, roots and the corolla of an Aponynaceae flower. Feeds by scratching in leaf litter and picking up food items from forest floor; also pecks at low-flying insects.

Breeding. Breeding season uncertain. Males call and maintain display scrapes, which are areas of forest floor cleared of leaf litter; both activities performed unpredictably and infrequently, possibly in relation to fluctuations in food supply. Only four nests have been described: in Mar. Apr and Aug in different years; two nests were simple, one a slight depression on top of a termite mound, and the other involved an egg-laid directly onto leaf litter amongst understorey plants. The only pheasant species definitely known to lay a clutch of 1 egg; incubation 22-23 days (in captivity); chicks have rather pale chestnut brown down above, buff below.

Movements. Appears to be sedentary. Bimonthly home range of three non-calling males was 10.8-58.3 ha, and of females 7.3-25.8 ha. Shifts of core area occurred within this home range.

Status and Conservation. Not globally threatened Mace-Lande: Vulnerable. CITES II. Survival of species probably depends upon future of lowland primary forest below 300 m (or maybe 150 m) in Peninsular Malaysia; one possible site in Thailand, no recent information from Burma. Based on recent fieldwork and extent of habitat remaining, population estimated to be in the thousands. Species present in Taman Negara National Park (4343 km²), Krau Wildlife Reserve (530 km²), Sungai Dusun Wildlife Reserve (45 km²), Sungai Wildlife Reserve (25 km²) and Pasoh Forest Reserve (25 km²). It seems likely that at most 50-70% of the area included within these reserves supports habitat below 300 m, within the species' altitude limits. Restricted range; species occurs in a low priority Endemic Bird Area. Overexploitation for food, sport and bird trade have con-

tributed towards (near) elimination of species in Thailand; these threats are not currently of consequence throughout rest of species' distribution. In Peninsular Malaysia, habitat is becoming fragmented, due to conversion of forest to agricultural land, and species will probably be confined to five protected areas in future; three of these areas are small. An international studbook of captive individuals is maintained by New York Zoological Society/Wildlife Conservation International; this records 189 individuals in 35 institutions in 1993.

Bibliography. Baker (1928), Brunning (1977, 1983b), Chasen (1939), Collar & Andrew (1988), Davison (1979a, 1983a, 1983b, 1985a, 1986c), Davison & Scriven (1987), Gibson-Hill (1949), Holmes & Burton (1987), Humphrey & Bain (1990), Johns (1986, 1989), Lekagul & Round (1991), van Marle & Voous (1988), McGowan (1991, 1992a, 1993, 1994b), Medway & Wells (1976), Riley (1938), Robinson & Kloss (1921), Roles (1990), Round (1988), Searle (1986, 1989), Siti Hawa Yatim (1993), Smythies (1986), Stapel (1976), Wells (1985, 1990).

149. Bornean Peacock-pheasant

Polyplectron schleiermacheri

French: Éperonnier de Bornéo German: Borneopfaufasan Spanish: Espolonero de Borneo

Taxonomy. *Polyplectron schleiermacheri* Brüggemann, 1877, south-eastern Borneo.

Has been considered a race of *P. malacense*, but a phylogenetic analysis of male morphology indicates that it is better treated as a full species. Forms superspecies with *P. malacense*; some authors also include *P. emphanum*. Monotypic.

Distribution. Borneo. Exact distribution uncertain.

Descriptive notes. Male c. 50 cm (tail c. 20 cm); female c. 35.5 cm (tail c. 15.5 cm). Male has throat and centre of breast pure white, and metallic blue-green sides of breast; upperparts more rufous than in *P. malacense*, with smaller ocelli. Female lacks distinctive head markings, apart from white throat; more reddish than female *P. malacense*, with shorter tail; lacks ocelli on uppertail-coverts, and has smaller, ill defined ocelli on rectrices.

Habitat. Occurs in primary lowland forest, and is possibly limited to that lying on riverine alluvium in valleys.

Food and Feeding. No information available.

Breeding. No information available from the wild. In captivity: one female laid three 1 egg clutches; incubation 20-22 days.

Movements. No information available.

Status and Conservation. ENDANGERED. Mace-Lande: Critical. CITES II. Very poorly known, and no recent records from N Borneo; believed to have been eliminated throughout most of original range, e.g. no recent evidence from Muara Tehew in C Kalimantan, Balikpapan in E Kalimantan, or Paitan in Sabah. Reported recently from only two locations: one in W Kalimantan and another in E Kalimantan. Much lowland forest remains in Kalimantan, although if species is confined to alluvial forest then it is likely to have been eliminated from most of the major river systems in Kalimantan. Species is presumed always to have been very difficult to detect, possibly reflecting very low densities. Based on this, lost sites and habitat remaining, population is tentatively estimated to number no more than 1000 individuals. Not known from any protected area, but a thorough search of Gunung Palung Nature Reserve might prove fruitful. Extensive and continuous habitat loss and degradation are major problems facing the species. Surveys and research urgently required. Protected by Indonesian law.

Bibliography. van Balen & Holmes (1993), Collar & Andrew (1988), Davison (1986c), Denton (1978), Dutson (1990), Holmes (1989), Holmes & Burton (1987), Howman (1993), MacKinnon & Phillips (1993), McGowan (1992a), Smythies (1957, 1981), Wayre (1969), Wells (1985).

150. Palawan Peacock-pheasant

Polyplectron emphanum

French: Éperonnier napoléon German: Napoleonfasan Spanish: Espolonero de Palawan
Other common names: Napoleon's Peacock-pheasant

Taxonomy. *Polyplectron emphanum* Temminck, 1831, Sunda Islands or the Moluccas; error = Palawan.

Has occasionally been considered to form a superspecies with *P. malacense* and *P. schleiermacheri*. Monotypic.

Distribution. Palawan I. SW Philippines.

Descriptive notes. Male c. 50 cm (tail 24-25 cm), c. 436 g; female c. 40 cm (tail 16.5-17 cm), c. 322 g. Male is markedly different from all other members of genus; long, pointed crest, solid black underparts and shiny blue and green on mantle, upperwing-coverts and tertials characteristic; distinctive black and white face pattern. Female generally brown with scattered buff markings and ill defined, blackish subterminal patches on tail; face, lores and throat brownish white. Immature male similar to adult female, with black spots on wings and longer legs. Some captive-reared males have white eyebrow of varying prominence; distribution and frequency of this character in the wild is not known.

Habitat. Traditionally said to be restricted to coastal lowland forest, which has now mostly been logged. Several mountain sites within range are now known, from limits of disturbed forest up to c. 600 m.

Food and Feeding. No information available.

Breeding. No information from the wild. In captivity: clutch of 2 eggs; incubation 18-20 days, by female only; chicks have tawny brown down above, more buff-coloured below.

Movements. No information available.

Status and Conservation. VULNERABLE Mace-Lande: Endangered. CITES I. Little, if any, forest remains in level lowlands, certainly on E coast, and species now largely restricted to mountains.

Based on remaining habitat, population estimated at fewer than 10,000 individuals; must be declining, due to loss of habitat. In theory, all of Palawan is a Flora and Fauna Watershed Reserve; occurs in St Paul's National Park, although much of this park consists of limestone outcrops which carry unsuitable habitat; forest contained within penal colony at Iwahig, which does support species, would make an ideal protected area. Restricted range; occurs in Palawan Island Endemic Bird Area. Threatened by overexploitation for food and bird trade (birds recently reported in Puerto Princesa City); also loss and degradation of habitat. Surveys to S of island, around Brookes' Point and Quezon, may reveal that

species survives in good numbers. Present species has potential for use as a flagship in public awareness campaigns, tri-shaw painting, etc. Palawan Chapter of the Haribon Foundation, the major conservation non-government organization in the Philippines, is now active.

PLATE 59

Family PHASIANIDAE (PHEASANTS AND PARTRIDGES)
SPECIES ACCOUNTS

PLATE 59

Genus *RHEINARDIA* Maingonnat, 1882

151. Crested Argus

Rheinardia ocellata

French: Argus ocellé

German: Perlenfasan

Spanish: Argos Perlado

Other common names: Rheinard's/Ocellated Argus, Crested Argus-pheasant; Malaysian Argus (*nigrescens*)

Taxonomy. *Argus ocellatus* Elliot, 1871, Hue, Vietnam.

Genus name has frequently been misspelt *Rheinartia*, and even in past *Rheinhardius*, *Rheinardius*, *Rheinartius* or *Rheinhardius*, amongst others. Two subspecies recognized.

Subspecies and Distribution.

R. o. ocellata (Elliot, 1871) - C Vietnam and E Laos.

R. v. nigrescens Rothschild, 1902 - mountains in C Peninsular Malaysia, within Taman Negara National Park.

Descriptive notes. Male 190-235 cm (tail 150-173 cm); female 74-75 cm (tail 35-43 cm). Male unmistakable; rectrices are the longest feathers in any bird. Female has distinctive head pattern and barring on upperparts. First-year male similar to adult male but tail shorter; attains adult plumage in 3rd year, but tail increases with each moult, until 5th or 6th. Male *nigrescens* darker than that of nominate *ocellata*, with more regular, whiter spots, and longer, whiter crest; browner bill.

Bibliography. Anderson (1993), Anon (1989c), Banks (1993), Chasen (1939), Collar & Andrew (1988), Davison (1977, 1978a, 1979a, 1979c, 1979d, 1980c, 1980d), Davison & Scriven (1987), Eames *et al.* (1992), Gibson-Hill (1949), Harrison (1972), Jahouille (1926, 1930), King (1978/79), Medway & Wells (1976), Nguyen Cu & Eames (1993), Robson *et al.* (1989, 1993a, 1993b), Roles (1990), Seth-Smith (1932), Siti Hawa Yatim (1993), Wells (1985, 1990), Wildash (1968).

French: Argus géant **German:** Argusfasan **Spanish:** Argos Real
Other common names: Great Argus-pheasant, Argus Pheasant

Taxonomy. *Plusianus Argus* Linnaeus, 1766. "Tartaria Chinesi"; error = Sumatra. Extinct form *bipunctatus*, possibly from Tioman I off Peninsular Malaysia, has alternatively been considered a race of present species or a distinct species; known only from a portion of a single male primary of uncertain origin (see page 436). Two subspecies recognized.

A. a. argus (Linnaeus, 1766) - Malay Peninsula S from c. 14° N; Sumatra.
A. a. gravi (Elliot, 1865) - Borneo.

Habitat. In Malaysia, inhabits tall logged forest and unlogged primary forest at many

sites, from sea-level up to maximum of 1000 m, although upper limit varies with location. Widespread in Indonesian part of range, occurring in lowland forest up to 500 m in Sumatra, and up to 1500 m in Kalimantan.

Food and Feeding. A wide variety of plant and invertebrate remains have been found in droppings; mainly fruits of *Palmae*, *Annonaceae* and *Leguminosae*, including climbing and understorey species, as well as those of canopy and emergent trees; termites encountered in only 1 out of 138 droppings, but ants common. Forages solitarily, walking slowly and peeking at leaf litter, or scratching at the litter surface in order to see what is underneath.

Breeding. Season not recorded; eggs found from early Mar to early Jul in Peninsular Malaysia, late Jul in Borneo. Solitary and territorial; males call and maintain dancing grounds, usually from Jan.

Movements. No information on seasonal movements. Monthly home ranges of two males were of 1.0-2.7 ha during Nov-Jan; core areas smaller.

Status and Conservation. Not globally threatened. Mace-Land: Vulnerable. CITES II field surveys in Peninsular Malaysia indicate density of 4 birds/km²; population is large and species widespread, but habitat rapidly becoming fragmented. Based on available habitat, total population estimated to number more than 100,000 individuals, but involved in a steep decline, especially in Sumatra, e.g. now very scarce in heavily disturbed forests of Way Kambas National Park. S. Sumatra: in Indonesia, reckoned to be secure only in reserves and well managed forests. Presence confirmed at 12 sites in Thailand, from plains up to c. 900 m; in Malaysia found in 17 protected areas of varying status, although some seem very small for a bird of such large size; assumed to be present in most protected areas in Indonesia. Species is very vocal, giving impression that it is very common in variety of forested habitats. However, rapid rate of forest clearance throughout range, leading to extreme fragmentation of once continuous lowland forest, suggests that severe decline in numbers may occur within next one or two generations of species. Does not appear to recolonize areas quickly. Assessment of upper altitude limit of species in Sumatra is very important, as this will determine whether species occurs in protected areas and above areas where logging is commercially viable. Protected by Indonesian law.

Holothuriforms Baker (1928), van Baaren & Holmes (1993), Banks (1935), Bruu (1975), Chazotte (1935), Coombs & Rutter (1946), Davidson (1979a, 1980a, 1981a, 1982b, 1983, 1984, 1987), Davison & Scriven (1987), Gibson-Hill (1949), Holmes (1989), Holmes & Burton (1987), Humphrey & Bain (1980), Johns (1986, 1989), Lekagul & Round (1991), MacKinnon & Phillips (1993), Mann (1987), van Marle & Vocus (1988), Medway & Wells (1976), Robinson (1951a, 1951b), Robinson & Kloss (1921, 1924), Roles (1990), Seth-Smith (1925), Sin Hwa Yatin (1933), Smythies (1957, 1981, 1986), Wells (1985, 1990).

French: Paon bleu German: Pfau Spanish: Pavo-real Común
Other common names: Common/Blue Peafowl, Indian Peacock

Taxonomy. *Pavo cristatus* Linnaeus, 1758, *Inde Orientale*, Sri Lanka. Monotypic.

Distribution. Pakistan (E of R Indus) through most of India (S from Himalayas) to Sri Lanka; may still occur in Bangladesh.

Introduced to many parts of the world, but usually remains semi-feral

Descriptive notes. Male 180–230 cm (tail 40–45 cm, train 140–160 cm), 4000–6000 g; wing-span 130–160 cm; female 90–100 cm (tail 32.5–37.5 cm), 2750–4000 g; wingspan 80–130 cm. Unmistakable, very distinctive crest. Female distinctive, with white belly. Second-year male resembles adult male, but train shorter and lacks ocelli; length of male's train increases with age, markedly so up to 4th year. Common captive form '*nigrispinus*' has scapulars and upperwing-coverts mostly black, labial

Habitat. Favoured habitat in N India appears to be open forest with ber (*Zizyphus*) undergrowth along streams; in S India, uses wide

range of habitats including secondary vegetation, orchards and other cultivation near villages, generally preferring moist and dry deciduous forests near streams; (occurs up to 2000 m.

Food and Feeding. Omnivorous. Food taken ranges from grain to green crops to insects, small reptiles, mammals and even small snakes; prefers berries, drupes (e.g. *Carissa*, *Lantana*, *Zizyphus*). **Nest and Wild life.** Cultivated fields and fallow land may be visited for feeding. Forages in small groups, harem in breeding season, segregated parties of females with young, and males, outside breeding season.

Breeding. Season varies across range but seems to be related to wet season; in most of S India and Sri Lanka, apparently Jan-Apr; in Tamil Nadu (S India), Oct-Dec; in Himalayan foothills, possibly Mar-Apr, but usually Jun. Polygamous. Nest usually concealed in scrub (*Lantana*, *Zizyphus*), but somewhat elevated in flood-prone areas. Usually 3-6 eggs (up to 8); incubation 28-30 days, by female only; chicks have dark brown and rufous down above, pale buff brown below.

Movements. No reliable information, but presumably sedentary, with small groups present in same area throughout year. Introduced population of Australia sedentary, but occasional movements of a few kilometres have been recorded.

Status and Conservation. Not globally threatened. Mace-Landse: Safe. No detailed information on status in India, as bird is considered so common that it is often overlooked as a rarity. In study, locally very common in Sri Lanka, e.g. in Yala, Bundala and Wilpattu Parks; in contrast, may have become extinct in Bangladesh, where was formerly common. The national bird of India. It is afforded protection throughout the country; in many areas it is protected because of its religious importance to both Hindus and Buddhists, who consider it sacred. Consequently, species lives in close proximity to human settlements, and is often found around villages and temples. As also minibus scrub, forest, semi-arid areas and cultivation, species is not considered in need of any conservation attention.

Bibliography Allen & Ripley (1980), Baker (1930), Chaudhry (1993), Gaston *et al.* (1981a, 1981b), Hannote *et al.* (1993a, 1993b), Harvey (1990), Hogg (1971), Hogg *et al.* (1983), Hogg & Ingleton (1989), Hogg *et al.* (1980), Lamb (1980), Lever (1987), Marchant & Higgins (1993), Manen (1951), Petrie *et al.* (1990), Phillips (1978), Rames *et al.* (1984), Ruffey *et al.* (1984), Roberts *et al.* (1984), Sauer *et al.* (1980), Sauer *et al.* (1986), Sutherland (1997), Sutherland & A. Vegetation Index, National Vegetation Survey, Panegy (1989), Zacharias & Gaston (1993).

154. Green Peafowl

Pavo muticus

French: Paon spicifère German: Ährenträgerpau Spanish: Pavo-real Cuelliverde
Other common names: Green-necked Peafowl, Green Peacock

Taxonomy. *Pavo muticus*. Linnaeus, 1766, Japan; error = Java.

Three subspecies recognized.

Subspecies and Distribution.

P. m. spicifer (Shaw & Nodder, 1804) - NE India and SE Bangladesh to NW Burma (possibly extinct).

P. m. imperator Delacour, 1949 - Burma S to Isthmus of Kra and E through Thailand to S China, Vietnam and Laos; patchy distribution.

P. m. muticus Linnaeus, 1758 - locally in Java; extinct in Peninsular Malaysia, and probably also in Thailand.

Descriptive notes. Male 180-250 cm (tail 40-47.5 cm, train 140-160 cm), 3850-5000 g; female 100-110 cm (tail 40-45 cm). Unmistakable. Female similar to male but shorter-legged, not so brightly coloured, and lacks long train of uppertail-coverts; dark chestnut-brown patch on lores; usually has spurs. Second-year male resembles adult male but has no ocelli in train. Races vary slightly in coloration; SE race *muticus* is brightest and greenest; NW race *spicifer* is duller, with upwing blacker and bluer, especially in male.

Habitat. In Java occurs in open woodland and at forest edge, but not inside rain forest, from sea-level up to 3000 m; also inhabits montane grassland above 2000 m. Found in riverine forest in Thailand.

Food and Feeding. Little known. Crops found to contain mainly termites, but also berries, grass seeds, peppers, flower petals, crickets, grasshoppers and small moths.

Breeding. In NE India, *spicifer* apparently breeds in Jan-Apr, but Jul-Sept also recorded; Apr-May in Bangladesh; in Java, *muticus* nests in Aug-Oct. Nests on ground, usually in sites that are well protected but with good visibility. Clutch of 3-6 eggs; incubation 26-28 days, by female only; downy chicks similar to those of *P. cristatus* but larger and greyer.

Movements. Believed to be fairly sedentary.

Status and Conservation. VULNERABLE. Mace-Lande: *muticus* endangered; *imperator* endangered; *spicifer* insufficient information. CITES II. Populations probably highly fragmented throughout range, and species may be more seriously threatened than available information indicates. Nominate *muticus* presumed extinct in Peninsular Malaysia (since 1960's) and probably also in Thailand. Now known only on Java, where has recently been found at 17 sites; a recent survey estimated population to number no more than 1000 birds; highly fragmented, and secure in only 3-4 areas; protected by Indonesian law, but some illegal trapping may continue; train feathers are used in traditional Javanese dances; this race present in Ujung Kulon National Park (761 km²), Baluran National Park (250 km²), Meru Betiri National Park (500 km²), Alas Purwo National Park (620 km²), Leuweng Sancang Nature Reserve (21 km²), Yang Nature Reserve (15 km²), Ijen Nature Reserve (25 km²) and proposed Cigong Nature Reserve (141 km²). In Thailand, *imperator* believed to be restricted to Huai Kha Khaeng Wildlife Sanctuary in W, while unconfirmed at three further sites: Thai population estimated to number c. 300 individuals. Total population of this race in thousands. Known from 10 sites in Tibet and a total of 9 contemporary sites are listed for Vietnam; occurs in several protected areas, in addition to Thailand's fully protected Hua Kha Khaeng (2575 km²); in Vietnam, found in Nam Bai Cat Tien National Park (350 km²), where up to 17 calling males were recently heard, just outside Bach Ma National Park (190 km²), and within Yok Don Reserve; in Laos, occurs in Xe Pian proposed protected area. Threatened by overexploitation for food and bird trade, habitat loss and degradation. Informed opinion suggests that *spicifer* is possibly extinct in both Bangladesh, where formerly a rare breeding resident in SE hill tract forest, and in India; no recent information from Burma; at best, this race is probably very rare.

Bibliography. Ali & Ripley (1980), Anderson (1993), Baker (1928, 1930), van Balen & Holmes (1993), van Balen *et al.* (1993), Chasen (1939), Cheng Tso-hin (1987), Collar & Andrew (1988), Deignan (1945), Eames *et al.* (1992), Gibson-Hill (1949), Harvey (1990), He Fen-qi *et al.* (1990), Hillgarth & Stewart-Cox (1986), Holmes (1989), Hoogerwerf (1949), Humphrey & Bain (1990), Indrawan (1992b), Indrawan & van Balen (1991), Inskipp & Inskipp

(1993b), King (1978/79), Lamba (1980), Lekagul & Round (1991), MacKinnon (1988), MacKinnon & Philipps (1993), Medway & Wells (1976), Meyer de Schauensee (1984), Nguyen Cu & Eames (1993), Robinson (1915a, 1915b), Robson *et al.* (1989, 1993a, 1993b), Round (1988), Sarker (1986), Siti Hawa Yatim (1993), Smythies (1986), Stewart-Cox & Quinell (1990), Zheng Guang-mei & Zhang Zheng-wang (1993).

Genus *AFROPAVO* Chapin, 1936

155. Congo Peafowl

Afropavo congensis

French: Paon du Congo German: Kongopfau Spanish: Pavo-real del Congo
Other common names: African Peafowl, Congo Peacock

Taxonomy. *Afropavo congensis* Chapin, 1936, Zaire, possibly upper Lukene River.

Only pheasant in Africa; affinities unclear, but probably closest to *Pavo*, although close relationships with Numididae and Cracidae also proposed. Monotypic.

Distribution. C & CE Zaire.

Descriptive notes. Male 64-70 cm (tail 23-26 cm), two birds 1361 and 1475 g; female 60-63 cm (tail 19.5-22.5 cm), two birds 1135 and 1154 g. Unmistakable. White bristles on crown of male sometimes very short; variable extent of naked red skin on neck. Female usually has spurs. First-year male duller, with back tinged brown; adult plumage attained in 2nd year.

Habitat. Inhabits primary lowland rain forest below 1200 m.

Food and Feeding. Believed to be omnivorous. Identified items include drupes of *Celtis ituriensis*, a common broad-leaved tree; also

aquatic insects and termites. Presence of termite larvae in gut contents suggests that birds may dig into termite mounds.

Breeding. Little reliable information from the wild, although it has been suggested that breeding may occur at any time, depending upon local rainfall conditions; 300 km S of equator, young birds found in Jan-Feb. In captivity often nests in trees, less than 1.5 m above the ground, laying eggs on concave platform rather than in true nest. Clutch usually of 2-3 eggs (up to 6); incubation 27-28 days; chicks have black and blackish brown down above, bright creamy yellow below, with cinnamon wings.

Movements. No information available.

Status and Conservation. INSUFFICIENTLY KNOWN. Mace-Lande: Insufficient information. Protected by law in Zaire since 1938. A very poorly known species, described less than 60 years ago; very difficult to detect and rarely seen in the wild; no records since an observation in 1982; unconfirmed sighting in Kahuzi-Biega National Park, Kivu, in early 1980's. Occurs in Maiko and Salonga National Parks and Ituri Forest, a recently declared national park, whence species was described. Threatened by logging and other pressures on forest resulting from expanding human population; known to have been snared for food and this practice apparently still continues where species persists; believed to be absent from areas within 25 km of each village and road by late 1950's and mid-1960's. Species is present and breeds in several collections, but successful pairing apparently difficult to achieve in captivity. An international studbook for species is held by Antwerp Zoo, Belgium; in Dec 1991 it recorded 64 males, 30 females and 3 unsexed young.

Bibliography. Appelman (1961), Assink (1991), van Bemmelen (1961), van den Bergh (1975), van Bockstaele (1988), de Boer & van Bockstaele (1981), Chapin (1936, 1938, 1937, 1942, 1948, 1953, 1954), Collar & Andrew (1988), Collar & Stuart (1985), Cordier (1949a, 1949b, 1959), Crandall (1949), Durrer & Villiger (1975), Ghigi (1949), Gysels & Rabaeu (1962), Hachisuka (1937), Hostie (1955a, 1955b), Hulsemans (1963), Jeggo (1972), Lippens & Wille (1976), Lovel (1976), Lowe (1938), Mackworth-Præd & Grant (1970), Prigogine (1953, 1956, 1971), Roles (1990), Schouteden (1937), Snow (1978), Taibel (1961), Urban *et al.* (1986), Verheyen (1956, 1962a, 1962b, 1965a, 1965b), Verschuren (1975, 1978).

Class AVES
Order GALLIFORMES
Suborder PHASIANI
Family NUMIDIDAE (GUINEAFOWL)

- Medium-sized, plump terrestrial birds, with small head, and extensive bare skin on head and neck; most species with crest or bony casque.
- 40-72 cm.

- Afrotropical Region.
- Wide variety of habitats, from dense rain forest to semi-desert.
- 4 genera, 6 species, 19 taxa.
- 1 species threatened; none extinct since 1600.

Systematics

The guineafowl have traditionally been considered a subfamily of an expanded version of Phasianidae (see page 434), but recent studies based on differences in DNA indicate that family treatment is appropriate for the group. According to DNA sequences the Numididae diverged from the Phasianidae lineage some 38 million years ago.

The family Numididae is endemic to Africa, and its closest relatives are apparently to be found in Phasianidae and Cracidae. It seems most likely that the guineafowl originated in the savanna zones of Asia, from a francolin-like phasianid, which probably colonized Africa some time around the middle to late Miocene. The changes in the distribution patterns of vegetation over geological time, determined by fluctuations in the climate and also by geological activity, influenced the taxonomic development of the ancestral guineafowl by causing a considerable degree of radiation. This, in turn, has led to the various representatives of the family occupying practically all of the biotopes found in Africa in the present day (see Habitat).

All four of the genera currently recognized within the guineafowl were clearly differentiated by the Pleistocene. Of the four, *Agelastes* is probably the most primitive. Its two species constitute a superspecies. The little known Black Guineafowl (*Agelastes niger*) was formerly awarded a separate genus, *Phasidus*, but in the early 1960's a detailed comparison of this species and the White-breasted Guineafowl (*A. meleagrides*) led to the conclusion that the two species were closely related, and should be united in a single genus.

Over the years, the Helmeted Guineafowl (*Numida meleagris*) has been subdivided into some 30 subspecies, but at present only nine are generally recognized, due to extensive intergradation. Two or sometimes three of these races have actually been considered separate species by some authors, and, while there is only limited support for this approach, there are three fairly clearly defined subgroups, with the nominate form occupying East Africa, the *galeata* group in West Africa, and the *mitrata* group in southern Africa. As in many similar cases, it is essentially a matter of personal preference as to whether these groups are treated as megasubspecies or allospecies, but zones of intergradation and the element of caution both argue in favour of the former.

The Plumed Guineafowl (*Guttera plumifera*) and the Crested Guineafowl (*Guttera pucherani*) form another super-

species. Some authors have preferred to recognize three species in the genus *Guttera*, dividing the Crested Guineafowl into two, with the promotion of the race *edouardi*, but once again extensive interbreeding, both in the wild and in captivity, has shown that they should be considered conspecific, although they have perhaps moved some little way towards speciation. About 15 subspecies have been described for the Crested Guineafowl, but currently only five of these are usually accepted.

While there is a certain amount of disagreement at the specific and subspecific levels, the four genera appear to be rather well defined, even if their relationships with one another are generally none too clear. Although the Helmeted Guineafowl has been known to hybridize with the Vulturine Guineafowl (*Acryllium vulturinum*) in captivity, the resultant young are sterile.

Morphological Aspects

Although the guineafowl constitute a distinctive group within the Galliformes, in structure and morphology they are generally rather similar to most other members of the order.

In the guineafowl, size appears to be related to the density of the vegetation in the habitats typically occupied by each species. Thus, the White-breasted, Black and Plumed Guineafowl, the species that frequent the areas with the thickest vegetation cover, are the smallest, with average wing lengths of about 20.5 cm for the first two species, and 22.5 cm in the last. The Crested Guineafowl, which inhabits areas with medium to high vegetation density, has a mean wing length of 24.5-26 cm, whereas the equivalent figure for the Helmeted Guineafowl of open or relatively open habitats is 25-28 cm. Finally, the largest species, the Vulturine Guineafowl, occupies open, arid ground and has a mean wing length of 29.5 cm.

Like other Galliformes, guineafowl are rather corpulent birds. The oval body is voluminous, exaggerating the bird's relatively small head. In all species, both the head and the neck are virtually featherless, and the bare skin is often beautifully coloured. The bare skin appears to play an important role in thermoregulation. It is also contorted into a whole series of adornments, including cartilaginous gape wattles, notably in the Plumed Guineafowl, folds of skin, for instance on the hind-neck of the Crested Guineafowl, warts on the cere, and cartilaginous bristles. As their vernacular names suggest, the

The presence of a bushy crest is one of the most characteristic morphological features of the genus *Guttera*, distinguishing its members from the other guineafowl. This genus is nowadays considered to comprise only two species, although until recently the normal version accepted three, as the widespread Crested Guineafowl was regularly split into two, with the recognition of a separate species for populations from Somalia south to central Tanzania. However, extensive morphological analysis has indicated that the two groups are best considered to form a single species with well marked subspecies.

Bruce Coleman]

Helmeted Guineafowl has a bony "helmet", whereas the Plumed and Crested Guineafowl have bushy crests.

The long, incredibly slender neck of the Vulturine Guineafowl has almost certainly developed in order to enhance the bird's visibility over vegetation. The aspect is strikingly exaggerated by a series of long, elegant ornamental plumes which hang down over the breast and upper back.

All these adornments are amongst the most distinctive features of the different species or, in some cases, subspecies. The many races of the Helmeted Guineafowl are generally separated on the length and shape of the bony casque and of the gape wattles, and also on the presence or absence of cere bristles and filoplumes on the hindneck.

The bill is usually short and stout, with the upper mandible curved. It is particularly feeble in the Black Guineafowl, but, in contrast, appears really quite robust in the Vulturine Guineafowl, an effect again enhanced by the very thin neck.

The wings are rather small and rounded, clearly belonging to non-migratory birds. They are designed for short bursts of rapid flight, enabling the birds to make a quick escape when danger threatens, but are quite unsuitable for any form of sustained flight. This is again typical of galliform birds, as is their style of flight, involving an explosive take-off and a series of rapid, powerful wingbeats, followed by a glide down into cover. In line with the limited flying abilities of the guineafowl is their short tail, composed of 14-16 rectrices. The exception is the Vulturine Guineafowl, which has a relatively long tail, particularly the central tail feathers.

The tarsus is strong and generally fairly short, although once again the Vulturine Guineafowl is an exception, as it has rather long tarsi. The legs and feet, with three front toes, a single hind one and strong claws, are perfectly adapted to a terrestrial lifestyle, and reflects the fact that guineafowl mostly move about by walking.

Agelastes is the only genus in which birds sport spurs; these sprout from the tarsometatarsus as in the junglefowl (*Gallus*), not from the hypotarsal ridge as in most other Phasianidae. Males of *Agelastes* can have one or two spurs per leg, as also do a few females. The Vulturine Guineafowl commonly has a strange series of spur-like bumps along the rear face of the tarsus, the function of which is unknown. They are generally longer in males than in females, and vary individually both in

size and in number, with up to six recorded. *Agelastes* again differs from the other guineafowl genera by having the tarsal scales imbricated and in rows, as in the francolins. The other genera have the tarsi covered with pentagonal scales which are not lined up in rows.

Plumage is generally black or dark grey, although in all species, except the two members of the apparently primitive genus *Agelastes*, this is heavily spotted or vermiculated with white. There is sometimes a bluish tinge to the plumage, which is typically produced by the feather spotting being bluish white, rather than pure white, but there are fairly extensive areas of rich blue on the underparts of the Vulturine Guineafowl.

In all species, sexual dimorphism is limited merely to males being slightly larger than females, with no evident differences in plumage, which is in line with their tendency towards monogamy and also the participation of the male in the care of chicks (see page 440). During the breeding season, there is slight protuberance in the cloaca of males, at any rate in the Helmeted Guineafowl. However, there is no seasonal variation in plumage in any of the species.

Juvenile plumage tends to be rather similar to that of the adult, but generally drabber, often with a certain amount of brownish barring. However, the juvenile White-breasted Guineafowl, in addition to appearing generally duller than the adult, has the plumage pattern more or less inverted, since it is the belly that is white, not the upper breast or upper back, as in the adult. Most of the rest of the plumage is brownish black, but recent evidence indicates that the feathered head and neck almost certainly retain the patterned natal plumage until the bird moults into full adult plumage, as is the case in other guineafowl. The juvenile Black Guineafowl likewise shows a white belly.

There is very little information available about moult in the Numididae, but the Helmeted Guineafowl is known to undergo a complete post-breeding moult, with the flight-feathers apparently replaced in serially descendant order.

Habitat

The natural distribution of the guineafowl is restricted to sub-Saharan Africa, except for an isolated population of the

Helmeted Guineafowl in north-west Morocco. Between them, the different species occupy almost all available habitat types, from dense rain forest to arid steppe and semi-desert. They can be found from sea-level up to considerable altitudes, and the Helmeted Guineafowl even occurs at 3000 m.

The White-breasted, Black and Plumed Guineafowl occupy areas of tropical forest, essentially in the equatorial belt. They are generally restricted to undisturbed primary forest, although the Plumed also occurs in very mature secondary growth, while the White-breasted has been seen in selectively logged forest. The secretive nature of these species, together with the difficulty of their observation, means that even basic knowledge on habitat use remains rather limited.

In terms of habitat preference, the Crested Guineafowl can be considered somewhat intermediate, as it occurs in secondary and riparian forest and also along the forest edge. Much the most widespread member of the family, the ubiquitous Helmeted Guineafowl, in addition to its isolated Moroccan population, is found in almost any form of open country from the Sahel zone southwards. Its most typical habitats include relatively open savanna and mixed areas of savanna and bush, sometimes interspersed with cultivation, but it is also common in savanna woodland and along forest edge. Finally, the Vulturine Guineafowl is the species that occurs in the driest, most open habitats. It is typically found in rather arid zones, including mixed *Acacia* and *Commiphora* scrub and semi-desert, although it does also occur in woodland, thickets and even montane forest.

As can be seen, there is a certain amount of overlap between the habitat preferences of the different species, and in some cases more than one species can occur in a particular area. For instance both the Vulturine and White-breasted Guineafowl coincide with the Crested Guineafowl, although in very different habitats, separated almost by the full breadth of Africa. Nevertheless, in such cases of overlap, the different species do not tend to associate with one another, and only rarely do they mix.

The proximity of water-holes, or other sources of drinking water, seems to be a limiting factor in the distribution of guineafowl, with the exception of the Vulturine Guineafowl. This species has an exceptionally long caecum constituting over

23% of the entire length of the intestines, and this may permit it to regulate and limit water loss. Another requirement, for all species, is the presence of suitable trees for roosting in at night.

General Habits

All guineafowl species have highly terrestrial lifestyles. They fly only rather infrequently (see Morphological Aspects), normally either up onto their roosts at night, or in order to escape from predators, although in the latter case they often prefer to run off at great speed.

They are gregarious for most of the year, but when the breeding season approaches, the flocks disperse, so that only solitary individuals or pairs are seen, or the odd small group perhaps composed of non-breeders. The flocks are governed by a complex social structure, and research on the Helmeted Guineafowl has shown that, at least in this species, individuals can remain in the same flock over a period of several years.

Group size, outside the breeding season, varies quite considerably with the species, from the Black Guinea fowl, which normally forms groups of under ten individuals, to the Helmeted Guineafowl, which can gather in large flocks of over 200 birds, although this species usually occurs in much smaller flocks of 15-40 birds. The other species form flocks of intermediate size. There is no evidence to suggest that flocks have strictly defined territories, and the ranges of two neighbouring groups can overlap to some extent. Nevertheless, if, for example, two flocks of White-breasted Guineafowl meet, a fierce fight is likely to ensue. In contrast to this, several flocks of Helmeted Guineafowl can coincide at drinking sites, particularly good feeding areas, preferred dusting sites, or roosts, but these flocks will only defend their own particular territories on rare occasions, for instance where the population is exceptionally dense.

The various different species of guineafowl have to be constantly alert to the threat posed by their many potential predators (see Breeding), although there are different ways of dealing with such threats when they actually materialize. For instance, when a predator approaches a flock of White-breasted Guineafowl, they separate and scatter until the danger has passed, when they regroup with the help of a cheeping call. In contrast to this rather passive strategy, a flock of Helmeted Guineafowl will sometimes perform communal defence against a predator.

The evidence available suggests that all species roost in trees at night, on the whole communally. Helmeted Guineafowl sometimes use traditional roosting sites over such long periods that the accumulation of dried out droppings on the ground below has been known to build up to over 30 cm deep! However, similar persistence has not been recorded for the other species. Thus, the White-breasted Guineafowl, for example, seems simply to choose a roost-site every evening in whatever area it happens to be at the end of the day, without there being the slightest evidence to suggest that such sites may be reused. The Plumed Guineafowl uses a different tree each night, whereas the Crested Guineafowl may regularly roost in the same general area. On occasions when there may be no suitable roosting trees in the vicinity, the Helmeted Guineafowl, at least, will look for some sort of substitute, and this species has even been observed roosting on telegraph poles.

Despite their apparent reluctance to fly, guineafowl are highly mobile birds, and they tend to spend the greater part of the day roaming about their territories, searching for food. For instance, White-breasted Guineafowl spend at least 60% of the day feeding, 20% preening, 11% in trees or flying, and the rest of their time engaged in other assorted activities.

The daily routine of activities in the Helmeted Guineafowl, the best known species, is rather well established, varying little from one day to the next. The roosting site is occupied in the evening, and the birds remain there until dawn, when they set off for their drinking holes, already starting to feed on the way. Often, they move about in "Indian file", with all members of the flock following on behind the dominant male. During the hottest hours of the day, they give up feeding and concentrate on drinking, and sand- or dust-bathing, which frequently takes

Although, like most Galliformes, guineafowl are essentially terrestrial in most of their habits, they are well adapted to perching in trees, as demonstrated by this Plumed Guineafowl. Apparently, all members of this family regularly roost in fairly tall trees, normally in communal groups, both of which tendencies are very likely to help in reducing the risk of predation.

[*Guttera plumifera plumifera*.
Photo: Bruce Coleman]

Unlike the other members of the Numididae, the Vulturine Guineafowl presents a rather beautiful and even spectacular plumage. While it shares with most of the other species the generally blackish background colour with a plentiful spattering of small whitish dots, it shows an extensive area of rich blue on the underparts, as well as a small patch of dark chestnut down on the nape. However, it is the well developed black and white hackles that really stand out, and intensify the effect of the bird having a very long, slender neck; hackles are particularly long, thin neck feathers that are found most typically in the Galliformes. All guineafowl have the head and neck virtually devoid of feathering, which is thought to be an important feature in thermoregulation.

place at traditionally favoured sites. Then they pass on to the business of preening and oiling. After this, they head for a suitable area in the shade of some vegetation, where they rest, using various devices to reduce body temperature, including gular-fluttering, and also holding the wings away from the body and moving them from time to time for ventilation. As the heat of the day begins to ease off, the birds renew their activity and, having revisited the drinking hole, carry on feeding until it is time to return to the roost. Other activities that are performed somewhat less regularly include basking in the sun, seeking better shade and day-time roosting, as well as courtship display and even attempted copulation. In the feeding areas disputes sometimes break out, and these become increasingly common as the breeding season approaches.

Voice

Guineafowl are gregarious species that inhabit areas with vegetation that is thick enough to make visual contact between the different members of a flock rather difficult. They overcome this problem by means of a full vocal repertoire, which enables a sufficient degree of communication to meet their ordinary needs. For this reason, most activities have associated vocalizations, which can vary according to the different forms of behaviour involved.

When a White-breasted Guineafowl comes across a plentiful supply of food, it will often communicate its discovery to the rest of the flock by means of a call known as "food muster", summoning its companions to share the food. The contact calls and leaf scuffling typically used by this species can be heard about 30 metres away, although some of its other calls are louder. Apart from feeding and contact calls, other typical call types recorded in various species include, not surprisingly, those to signal alarm and others used in moments of aggression.

There are some differences between the sexes in vocalizations. For example, females of both the Vulturine and Helmeted Guineafowl have a "buck-wheat" call, which they most typically use during the breeding season, on occasions when they are separated from their partners.

Food and Feeding

The evidence available suggests that all guineafowl are omnivorous opportunists. The composition of their diet at any

particular moment is dictated by the local abundance of the various different food types, with the result that their daily wanderings in search of food can vary considerably, in terms of both time and direction.

Overall, the diet is very varied, and plant matter taken includes roots, bulbs, seeds, fruits, leaves and flowers. In some cases, the Crested and Helmeted Guineafowl, in particular, come into conflict with local farmers for their attacks on crops, although the overall effects of their presence in cultivation may not actually be detrimental (see Relationship with Man). Animal food consumed consists mainly of invertebrates, including a very wide array of insects, and also small molluscs, arachnids and millipedes; a few vertebrates are also eaten, for instance small frogs and toads. Birds also take in variable quantities of grit, which enable them to grind down their food more efficiently.

Some species, most notably the Helmeted Guineafowl, seem to prefer to feed on insects, when they are sufficiently abundant, and the crop of one individual examined, for example, was found to contain something in the region of 5100 harvester termites (*Hodotermes mossambicus*), which together weighed 243 grams. Nevertheless, in this same species it has been found that there is a tendency for considerable individual variation in feeding intensity, and crop contents can vary markedly between different members of a single flock.

In general, it is essential for guineafowl to have access to some source of drinking water, which they tend to visit regularly (see Habitat, General Habits). The exception, the Vulturine Guineafowl, of more arid zones, appears to be totally self-sufficient in this department, and it does not even seem to take the opportunity to drink when it comes across standing water, even at the height of the dry season.

All species feed almost exclusively on the ground, although the Crested Guineafowl has, on occasions, been seen feeding on fruits in trees. Similarly, the Vulturine Guineafowl occasionally climbs into low trees or bushes to feed on fruits, for example of *Salvadora persica* and several species of *Commiphora*. The Helmeted Guineafowl often strips the seeds off grass, or crops such as sorghum and millet.

Birds look for food as they walk along, pecking here and there, when they come across anything edible. They frequently use the feet to dig food out from under the ground, and with their strong claws they scrape away at the soil and the leaf litter. They may scrape with both of the feet alternately, or with only one foot, and all the while they peck at any food item that is unearthed. Only if the soil is soft enough will they also scrape about and even dig with the bill.

The curved bill enables the birds to reach and dig out underground bulbs and roots, which, in addition to forming a complementary source of nutrition, may be important in constituting an extra source of water, particularly during dry seasons.

The amount of food consumed by each individual seems to be inversely proportional to the distance covered during foraging. Thus, in areas with a rich supply of food birds tend to move slowly over fairly short distances, but where food is scarce they normally move much more quickly about over a much greater area.

As is the case of most birds and mammals in the tropics, feeding activity seems to be most intensive in the early morning, just after the birds have left their roosts, and again in the mid-afternoon and early evening. This is, of course, a consequence of the necessity to avoid the worst of the midday heat, when the birds invariably move into the shade to rest, and occupy themselves with plumage care and other comfort activities (see General Habits).

An interesting aspect of the feeding behaviour of the Numididae is that, as well as being gregarious, they also associate with other species of birds or mammals, in order to improve their rate of foraging success. For instance, the Crested Guineafowl sometimes follows arboreal monkeys, feeding on the remains of food that the monkeys drop onto the ground. While the same association with monkeys has not been recorded for the forest-dwelling White-breasted and Black Guineafowl, the former has been seen

With its rather plump build, the Helmeted Guineafowl is by no means an agile flier, and, although it can fly quite rapidly for short bursts, its flight tends to be rather heavy. Thus, it is hardly surprising that the species prefers to flee its predators by running away at top speed, before plunging into the shelter and safety afforded by thick vegetation.

[*Numida meleagris*
mitrata, Zambia.
Photo: S. Robinson/NHPA]

feeding on the remains of food possibly dropped on the ground by monkeys or chimpanzees (*Pan troglodytes*). The same species is known to associate with certain forest passerines that feed on the ground or in the lower canopy, for instance pittas (*Pitta*), turdids (*Alethe*, *Cercotrichas*) and bulbuls (*Bleda*); in such cases, it is thought that the guineafowl is probably looking for insects that may be disturbed or dropped by the birds.

The Helmeted Guineafowl regularly associates with a variety of other animal species. In many areas, it habitually feeds and drinks alongside baboons (*Papio cynocephalus*), and both species often try to steal bits of food from each other. Another, probably even commoner, association is with Swainson's Francolin (*Francolinus swainsonii*), whereas less frequently this species also joins Sacred Ibises (*Threskiornis aethiopicus*) and even introduced Common Mynas (*Acridotheres tristis*); mammals with which it sometimes associates include rhinoceros, antelope, lion and mongoose. Obviously, at water-holes, it occurs alongside many more species, but this can not really be considered a true association.

Breeding

Very little is known about the breeding habits of most members of the Numididae, and in some cases the size and colour of the eggs constitute virtually the only information available. Thus, details regarding courtship display, the roles of the sexes, the incubation period, overall levels of success, and so on, can only be interpolated tentatively from the best known species, the Helmeted Guineafowl.

The seasonality of breeding does not appear to follow particularly well set patterns, and the genera *Agelastes* and *Guttera* can breed at any time of year. Nevertheless, there do tend to be certain seasonal peaks which are apparently related to the rains. Thus, the White-breasted Guineafowl seems to prefer the end of the rains, whereas the Black Guineafowl probably breeds mostly in the driest months of the year. The other four species generally show a greater or lesser tendency to nest during the rains. An interesting case is that of the Crested Guineafowl, as its populations living in the vicinity of the equator, where there are two wet seasons in the year, nest all year round.

The first signs of breeding can be in the form of increased frequency and intensity of aggressive behaviour, in particular fights between rival males, and the splitting off from the flock of pairs that have been established. Male Helmeted Guineafowl can associate briefly with a series of various different females, each in its own turn, over the first four to six weeks. After this period, the pair stabilizes and then remains firm until the end of the breeding attempt. As a result of this system, the business of establishing and maintaining the pair-bond causes considerable expenditure of energy by the male, and this is reflected by a loss of weight amounting to about 11%. Although there is no clearly defined territory, at any rate in the case of the Helmeted Guineafowl, throughout this initial period males are perpetually chasing each other and fighting, and frequent communication, both vocal and visual, between partners is essential for the maintenance of the pair-bond.

Courtship feeding is known to occur, at any rate in the Helmeted, Crested and Vulturine Guineafowl, and it is particularly ritualized in the last of these species. All three are monogamous, although males sometimes attempt to mate with other, unattended females. The Plumed Guineafowl is probably monogamous too, while individual males of the Black Guineafowl have been seen with two females.

No nest has ever been found for either the White-breasted or the Black Guineafowl, but they may well be similar to those of the other members of the family, which are very simple affairs. Essentially, the nest is a shallow depression in the soil, sometimes at the base of a tree or in long grass. It may be lined with a few dry leaves, perhaps a little grass, and sometimes the odd feather.

All species have pale eggs, ranging in colour from dirty white and cream to reddish or brownish, sometimes with a limited amount of spotting. The eggs are oval, with one end sharp and the other rounded. The shell is particularly thick, and its surface is pitted, with a dense covering of pores. It is said that the characteristics of the guineafowl egg would enable it to survive undamaged through a grass fire. Clutch size is normally of 4-19 eggs, but even larger clutches have been recorded, although these probably refer to cases of more than one female laying in the same nest. There is no record of any species ever laying more than a single clutch per season.

Descending from its roost early in the morning, the Crested Guineafowl dedicates most of the day to the search for food. Birds sometimes end up covering considerable distances daily in the process of foraging, although this, of course, depends largely on local food availability at the particular time. Once the midday heat sets in, birds tend to retire to some shady spot for repose, before proceeding forth again in the latter part of the afternoon.

[*Guttera pucherani*
pucherani, Kenya.
Photo: Roger Tidman/
FLPA]

Dust-bathing, or dusting, is one of the activities in which the Helmeted Guineafowl most commonly indulges. It serves to keep the plumage in prime condition, for instance by helping to remove parasites. Effective dusting often requires a certain amount of previous preparation, and a bird may spend some time breaking up the soil into a fine powder, so that it can more easily be dispersed throughout the plumage by means of jerks and wriggles of the body and wings.

[*Numida meleagris damarensis*, Etosha National Park, Namibia. Photo: Jeremy Woodhouse/DRK]

At any rate in the Helmeted Guineafowl, and probably also in the Crested Guineafowl, incubation is carried out entirely by the female, and during this period she hardly leaves the nest at all, while the male stands guard nearby, never letting his partner out of his sight. Incubation begins once the last egg has been laid, and lasts from 23 days in *Guttera* and *Acryllium* to 24–28 days in *Numida*.

Chicks, or keets, hatch synchronously, a common tendency in birds with nidifugous chicks, as it reduces the danger of predation. The precocial chicks are led away from the nest almost immediately, but, although they are capable of feeding themselves, they still require the guidance and protection of their parents for some time, and the male shares the tasks of chick-care with the female, at least in the Helmeted Guineafowl. In particular, during the first 12 days of the chicks' lives, the male takes on the burden of all the day-time brooding, while the female gradually recovers her strength and the weight she has lost during the formation and laying of the eggs, and also the entire process of incubation. At night, it is the female's turn to take on the entire responsibility of brooding the chicks, and the male goes off to roost with the rest of the flock. When the chicks are feeding, they are normally accompanied by both adults, but it is the female that acts as leader of the family group. At 15–20 days old, the chicks are already able to fly up onto roosts that are two metres off the ground.

When danger threatens, both adults take part in the defence of the chicks, the Helmeted Guineafowl often performing a frontal display with the wings spread and a growling threat, before launching into an attack. Guineafowl face a whole host of potential predators at the various different stages of breeding. For instance, various monkeys, genets and wild cats sometimes steal eggs, and the last-mentioned can even kill adults at the nest. Both the Black Crow (*Corvus capensis*) and the Lanner Falcon (*Falco biarmicus*) are known to take Helmeted Guineafowl chicks occasionally.

Once the breeding season draws to a close, the family group is merged into a much larger flock, consisting of other similar family groups and some non-breeding birds. Within this larger flock, the unity of the family group tends to persist, and the young birds remain in the company of their parents for at least two or three months more.

It has been calculated that, in an average population of Helmeted Guineafowl, during a normal breeding season, about 30% of the birds do not breed, although it is not known whether or not this percentage refers exclusively to immature birds. These non-breeders hang about in flocks in the habitual feeding areas, and later join up with the breeders when they return with their young. Although flocks are fairly stable, each individual does not necessarily return to the same flock that it belonged to before the breeding season.

Movements

All species of guineafowl are sedentary, and their movements are limited to the local ones that they perform daily, over variable circuits, in search of food and water. Although they are mainly terrestrial, they are surprisingly mobile on their feet, and the area in which they forage can vary quite considerably from one day to the next, when foraging success is low. Indeed, apart from the Helmeted Guineafowl, which is known to use traditional roosts (see General Habits), birds may start and end each day in quite different places.

The long, winding route followed daily by flocks of White-breasted Guineafowl, for example, takes them, on average, over an area of about 0.9 km². The speed at which the birds move about is directly related to foraging success, varying from 10 m/h to 203 m/h, with an average of 115 m/h. In the Helmeted Guineafowl, it appears that larger flocks tend to cover greater distances daily than smaller ones, although the relative proximity of roosting and drinking sites are also major factors. In this species, home range has been found to average about 8.8 km², although it is actually extremely variable depending on the habitat type.

Relationship with Man

The relationship of man with guineafowl goes way back into ancient times, mainly through the domestication of the Helmeted Guineafowl. Over the centuries, this species has probably been domesticated by several different peoples independently at different times.

Natural water-holes, and also those provided artificially for domestic livestock, are frequently used by Helmeted Guineafowl as habitual sources of drinking water. At such sites different flocks may come into contact with each other on a regular basis, and very large concentrations of birds may gather, although usually without any form of territorial dispute occurring. This species, the most gregarious of all the guineafowl, sometimes combined flocks of up to 200 birds or more.

[*Numida meleagris damarensis*, Savuti, Chobe National Park, Botswana. Photo: Richard Coomber/Planet Earth]

The earliest reference to guineafowl comes from murals of the Fifth Dynasty of Egypt in the Pyramid of Wenis at Saqqara, which date to about 2400 BC. The Phoenicians and Greeks are also known to have kept domesticated guineafowl, the latter from at least as early as about 400 BC. Only slightly later, in the fourth century BC, the Moroccan race *sabyi* of the Helmeted Guineafowl was considered a sacred bird on one of the islands of the Aegean. Subsequently, the Romans regularly kept birds of both this and the nominate race for food, and they carried both forms to all parts of their enormous empire. However, it seems that with the fall of the Roman Empire the species disappeared from Europe, and after this there was a long period in which it does not appear to feature in historical records, apart from an odd record of some captive birds in Athens in the tenth century AD. In the fifteenth and sixteenth centuries, the Portuguese explorers and navigators brought back individuals of the West African race *galeata* to Europe, and the species was regularly kept once again.

The repeated domestication of this species over many centuries has led to its presence practically all over the world, usually in domestic form, but in many cases with feral populations too. Such feral populations arose where a proportion of the domestic stock escaped and managed to establish more or less stable populations in the foreign habitat. This was the story, for example, on many islands in the West Indies, such as Cuba, whither the species was brought in 1508. Much of the importation of guineafowl to parts of Europe and especially America was effected by ships transporting slaves, and so many birds were imported that by the beginning of the eighteenth century feral populations had become established on most of the larger islands in the Caribbean. The species has also been introduced in several areas closer to home, for instance south-west Arabia, Madagascar, the west of Cape Province in South Africa, and several of Africa's outlying small islands. On the other side of the world, in Australia and New Zealand, there have been a multitude of instances over the years, at least since about the 1860's, of domestic birds escaping or being released, but they have invariably failed to become established, although in some areas birds live on in the vicinity of farms in a semi-domesticated state.

Guineafowl feathers have traditionally been highly prized as ornaments by the chiefs and witch doctors of some tribes.

In some areas, the birds were regarded as symbols of fertility, due to their profuse production of eggs, and these, in turn, were used in rites of initiation for young girls or newly-weds, or other, similar ceremonies.

Although guineafowl feathers were also used as adornments for women's hats in Europe, and the eggs came to form a part of a few local traditions in central Europe, man's main use for guineafowl has been as a source of food. Both the eggs and the flesh have been much appreciated by man probably since his first contact with them. The major consequence of this has been the breeding of guineafowl, invariably the Helmeted Guineafowl, on an industrial scale, and nowadays there are a great many farms dedicated to the production and commercialization of guineafowl. Proof of their wide culinary acceptance is supplied in the form of the surprisingly large number of recipes specifically for guineafowl that exist all round the world.

Within the natural ranges of the guineafowl, problems frequently arise due to a conflict of interests between man and the birds. Once again, it is mainly the Helmeted Guineafowl that is implicated, as this is the species that occupies the most similar habitat, and most readily occurs in cultivation. While farmers tend to consider the birds a plague, it seems that they should really be regarded as allies. While they will take a certain amount of some kinds of grain, the damage they cause to maize is virtually nil. At the same time they eat large quantities of destructive insects and also weeds, and thus collaborate significantly in the production of a healthy crop.

The Helmeted Guineafowl has recently been put to a new, rather revolutionary use in the USA, where it is now being employed in the control of infections spread by parasites, in this case those that produce Lyme disease. The parasites are spread by deer ticks, and until recently all attempts to control them had failed, but the release of the guineafowl in the infected area has proved very effective.

The generic name *Numida*, which also gives the name to the family, refers to the ancient North African state of Numidia, and illustrates the fact that from the point of view of the Romans the birds arrived from Numidia. The specific names *meleagris* of the Helmeted Guineafowl and *meleagrides* of the White-breasted Guineafowl are derived from the Greek hero Meleager, who hunted the great boar sent by Artemis to ravage

Calydon. Upon his death, his sisters were so grieved that they were turned into birds, the *meleagrids*, and their tears were transformed into white droplets all over their mourning dress. The birds that the Greeks referred to by this name were surely guineafowl, although it is equally sure that they were not White-breasted Guineafowl!

Status and Conservation

Of the six species of guineafowl, one is currently considered to be threatened, while the remaining species appear to be relatively secure. As a result of the recent Conservation Assessment and Management Plan (see page 472), which reviewed the status, threats and conservation requirements of all galliform species except the cracids, the situation of those species that are not considered to be threatened can now be viewed with a good deal more confidence.

Both the Helmeted and Vulturine Guineafowl are reckoned to have total populations numbering over a million individuals, and in the case of the former there are likely to be many millions. Populations of the very little known Black Guineafowl and also the Crested Guineafowl are both thought to be in the hundreds of thousands, and that of the Plumed Guineafowl in the tens of thousands. The one threatened species, the White-breasted Guineafowl, probably still numbers over 58,000 birds, but it is in constant decline.

The chief threats to the family as a whole seem to be habitat destruction and, in some cases, excessive hunting levels. Both of these factors are most serious in the cases of the forest species, and this is generally reflected in the population figures, as the species with the highest populations are those of open areas, while those of forest generally present much lower figures and are thought or known to be declining. Nevertheless, there are negative factors operating even on the Helmeted Guineafowl, the most serious of which is the increasing use of pesticides, which are likely to have adverse effects on the species in the long run. The Moroccan race *sabyi* of this species has declined drastically, for unknown reasons, and it may, in fact, already be extinct.

The main concern, however, must undoubtedly be for the prospects of the White-breasted Guineafowl, which is classified as Endangered, and is currently reckoned to be one of the most severely threatened species in the entire African continent.

The species is an inhabitant of one of the richest of African forests, the Upper Guinea Forest, which is famous for the large number of endemic forms it holds. This expanse of rain forest formerly spread over some 333,600 km², but it has suffered widespread devastation starting in the nineteenth century, and now occupies under 13% of the original area. Worst still, the habitat that remains is heavily fragmented into rather small pockets, which are spread over five different countries.

The other major problem that besets the species is excessive hunting pressure, in the form of both shooting and snaring. Such pressure has probably already led to some local extinctions and it threatens to bring about others in the not too distant future, especially in Liberia and Ghana. While many species are capable of withstanding a moderate level of hunting pressure, when this is combined with habitat loss and fragmentation, such large species can be systematically wiped out from each small pocket of forest until they disappear from whole areas. The situation is made all the worse by the ready availability of guns and cheap cartridges throughout Liberia, Ivory Coast and Ghana.

In Sierra Leone, the White-breasted Guineafowl occurs only in the Gola Forest, where it was first recorded in the late 1960's. There were very few subsequent records until an exhaustive avifaunal survey of this important site in 1988-1989 discovered that the species in fact occurs regularly throughout the forest. In the area around Mogbai, for example, it was recorded at densities of about 10-15 birds/km² in primary forest. Although it is also found in logged forest, it occurs at much lower densities of only 1-2 birds/km². The Gola Forest is protected with three reserves totalling some 748 km²; the limited hunting pressure that the species faces here suggests that this might be the healthiest population of all.

Due to many years of political unrest, the status of the species in Liberia is not well known, but as the forest is thought to be disappearing at a rate of about 5% per year, the situation is not encouraging. Indeed, the species is now considered rare.

Guineafowl nests are generally rather modest affairs, being simply a slight depression in the ground, sometimes under some vegetation cover, with or without a sparse lining of leaves, grass and perhaps feathers. The female Helmeted Guineafowl normally lays 6-12 eggs, which she herself incubates alone, although the male remains nearby. Incubation lasts 24-28 days, and does not start until the clutch is complete, thus favouring the synchronous hatching which is almost essential for those bird species that have nidifugous chicks.

[*Numida meleagris coronata*, South Africa.
Photo: J. J. Brooks/Aquila]

Guineafowl chicks leave the nest almost immediately after hatching. They are initially brooded and fed by the male, although in the Vulturine Guineafowl this may last only for the first few days, after which time the chicks are constantly accompanied by both parents. In this species, family groups tend to join up with other flocks of adults when the chicks are still in their first month. The chicks' flight-feathers are already well developed at ten days old, and at around eight weeks old the first of the characteristic blue underpart feathers begin to appear.

and to have disappeared from most of the country. It was thought to be extinct on Mount Nimba due to the opening up of the area for iron ore mining in the late 1950's and early 1960's, but it has recently been resighted there. There are also some fairly recent records from the Sapo National Park and the Grebo National Forest, but heavy hunting pressure may have eliminated the species from the latter.

In Ivory Coast, the species has not been seen anywhere outside the Taï National Park since the 1970's; like the Gola

Forest, the Taï can be considered one of the most important areas of forest in the whole of Africa, with a total area of 4060 km², including a buffer zone of 660 km². Recent surveys have revealed that the species is uncommon to rare, with an overall density of 16 birds/km², which has been extrapolated to give an estimated total population for this park of some 30,000-40,000 birds. While some hunting seems to occur, the scale of this is not yet known, although there is reason to believe that it may be fairly limited. Apart from survey work and proposals for protection, one of the major steps towards the conservation of the species involves the first significant studies of its biology and ecology, studies which were carried out in the Taï Forest from 1989 to 1991.

The remaining countries that fall within the White-breasted Guineafowl's range are Guinea and Ghana, but the population that was thought to occur in the south of the former has probably now been extirpated. In Ghana, too, the species was assumed extinct for some years, as there were no records at all between 1963 and 1985, but several recent records in different areas, including some parks, have proved that this is not the case. Nevertheless, the rampant deforestation and hunting that pervade these areas suggest that the outlook for the species in Ghana remains bleak.

The key to the survival of the White-breasted Guineafowl seems to be very clear. If large tracts of primary forest can be preserved relatively undisturbed, with hunting pressure reduced to a minimum, the species is unlikely to disappear. For this reason, every effort should be made to promote the strict protection of the Gola and Taï Forests, while the same could also be said for all other areas where the species is still known to occur in Liberia and Ghana. The preservation of these essential sites would assure the future of this and many other threatened species.

General Bibliography

Cracraft (1981), Crowe (1978a, 1978b, 1985), Crowe & Snow (1978), Ghigi (1936), Hastings Belshaw (1985), Mainardi (1963), Peters (1934), Raethel (1988), Rutgers & Norris (1970), Sibley & Ahlquist (1990), Sibley & Monroe (1990), Sibley *et al.* (1988), Stock & Bunch (1982), Urban *et al.* (1986), Verheyen (1956).

The White-breasted Guineafowl is currently considered to be one of the most threatened species in all Africa. It has a limited range in the Upper Guinea Forest of West Africa, where it is more or less restricted to primary rain forest, a habitat type that is rapidly being degraded or, in places, completely destroyed. Although the species is found in some protected areas, for long-term survival it will require a more extensive network of such parks, and more efficient protection, not only from the effects of habitat loss, but also from the considerable hunting pressure it faces.

5

Genus *AGELASTES* Bonaparte, 1850

1. White-breasted Guineafowl

Agelastes meleagrides

French: Pintade à poitrine blanche German: Weißbrust-Perlhuhn Spanish: Pintada Pechiblanca

Taxonomy. *Agelastes meleagrides* Bonaparte, 1850, no locality = Ghana.

Forms superspecies with *A. niger*. Monotypic.

Distribution. SE Sierra Leone through Liberia and Ivory Coast to W Ghana.

Descriptive notes. c. 40-45 cm; c. 815 g (in captivity). Head and upper neck bare; lower neck, breast and upper back pure white; rest of plumage black; 1-2 spurs. Female similar to male, but averages smaller. Juvenile generally dull brownish black, with some reddish brown feathers on wing and body; apparently retains juvenile down on head and neck, dark sepia with pale ochre stripes; lacks white collar, but belly pure white; spurless.

Habitat. Dense primary rain forest, with apparent preference for drier areas; also found in nearby patches of selectively logged forest, especially older regrowth, but presence of primary forest seems essential. Normally roosts in thin, shrubby trees in understorey of forest.

Food and Feeding. Mostly invertebrates, including termites, ants, crickets, millipedes, worms, beetle larvae (Chrysomelidae), spiders and small molluscs; also takes berries and seeds fallen off forest trees. Forages on ground, walking slowly along and stopping frequently to scratch in amongst soil and leaf litter with feet. When one bird finds abundant source of food, will often summon other flock members to join in.

Breeding. Oct-May, perhaps peaking at end of wet season Nov-Jan, but may breed throughout year. Nest undescribed. Clutch c. 12 eggs. Eggs reddish buff with white pores; 45 x 35 mm. Chicks have down greyish brown patterned with pale ochre, and dark sepia on head and neck. No further information available.

Movements. Sedentary. Short local movements over c. 0.9 km².

Status and Conservation. ENDANGERED. Mace-Landé: Vulnerable. One of most severely threatened species in Africa. Total population estimated at over 58,000 birds; undergoing major decline due to destruction and fragmentation of habitat, and also excessive hunting pressure. Probably occurred in S Guinea in past. In Sierra Leone, restricted to Gola Forest, where protected in three sizeable reserves; major survey in late 1980's found density of 10-15 birds/km² in primary forest; hunting pressure possibly lower here than anywhere else in species' range, partly because a cartridge costs more than the value of the bird, so hunters tend to concentrate on larger game; trapping also considered to be relatively unimportant. Has disappeared from most of Liberia; thought to have been eradicated on Mt Nimba in late 1950's and early 1960's, due to opening up of area for mining, but recently rediscovered; fairly recent records from Sapo National Park and Grebo National Forest, but may now have been eliminated from latter by intense hunting. In Ivory Coast, restricted to Taï National Park, where recent research and surveys carried out; density of 16 birds/km² giving possible overall population of 30,000-40,000 birds for park. In Ghana, was thought to be extinct, with no records after 1963, but several recent sightings: in 1985 at Bia; in 1988 in Mini-Suhien National Park; and in 1989 in both Boia-Tano and Tano-Anwia Forest Reserves, and further S at Enchi; nevertheless, deforestation and hunting particularly excessive throughout this zone, and future of species in Ghana remains precarious. Highly susceptible to pressure of hunting and deforestation; disappears from logged areas, or at best occurs at much lower densities, e.g. 2 birds/km² in Gola Forest; presence in secondary growth may require close proximity of undisturbed primary forest. Further surveys urgently required for more precise appraisal of total population size and requirements; other main recommendation is effective protection of maximum number of areas where species still occurs; campaigns to inform public and terminate hunting also highly desirable. CITES III in Ghana.

Bibliography. Allport (1991), Allport *et al.* (1989), Bannerman (1953), Bechinger (1964), Collar & Andrew (1988), Collar & Stuart (1985, 1988b), Colston & Curry-Lindahl (1986), Davies (1987), Dutton & Branscombe (1990), Francis *et al.* (1992), Garshore (1989), Gatter *et al.* (1988), Grimes (1987), Hall (1961), Mackworth-Praed & Grant (1970), McGowan, Carroll & Ellis-Joseph (1994), Taylor (1988), Thiollay (1985e), Urban *et al.* (1986).

2. Black Guineafowl

Agelastes niger

French: Pintade noire German: Schwarzperlhuhn Spanish: Pintada Negra

Taxonomy. *Phasidus niger* Cassin, 1857, Cape Lopez, Gabon.

Sometimes retained in monotypic genus *Phasidus*. Forms superspecies with *A. meleagrides*. Monotypic.

Distribution. SE Nigeria to N Angola (Cabinda), and eastwards N of R Congo to extreme NE Zaire. **Descriptive notes.** c. 40-43 cm; c. 700 g. Head bare, with short crest of black down; rest of plumage black, but centre of belly browner; 1-2 spurs. Female similar to male, but averages smaller. Juvenile has belly white; spurless.

Habitat. Dense primary rain forest, with possible preference for dense undergrowth; also occurs at forest edge in Gabon, and in abandoned cultivation in forest clearing in N Angola, but in Cameroon apparently restricted to forest interior.

Food and Feeding. Basically insects, with beetles, ants and termites recorded; other invertebrates such as millipedes and small frogs. Plant matter includes hard seeds, green leaves and fruits (e.g. of palm trees). Forages on ground, scratching with feet.

Breeding. In NE Zaire, breeds in almost any month, but mainly during drier months Dec-Feb; elsewhere little known, and birds captured Dec-Feb in Congo, and Sept in Angola were not in breeding condition. Nest undescribed, eggs pale reddish brown, sometimes tinged yellow or violet; c. 42 x 34 mm. Chicks mainly dark rufous and black above.

would be highly desirable, with a view to establishing suitable protected areas within its range; effective control of hunting seems necessary, at any rate in parts of range, in combination with campaigns of environmental education.

Bibliography. Ash (1990), Bannerman (1953), Chapin (1932), Lippens & Wille (1976), Mackworth-Praed & Grant (1970), McGowan, Carroll & Ellis-Joseph (1994), Pinto (1983), Rodewald *et al.* (1994), Surgeant (1993), Thiollay (1985e), Urban *et al.* (1986).

Genus *NUMIDA* Linnaeus, 1766

3. Helmeted Guineafowl

Numida meleagris

French: Pintade de Numidie German: Helmpferlhuhn Spanish: Pintada Común
Other common names: West African/Grey-breasted Guineafowl (*galeata*); Tufted Guineafowl (*mitrata*); Reichenow's Guineafowl (*reichenowi*)

Taxonomy. *Phasianus meleagris* Linnaeus, 1758, upper Nile, Nubia, Sudan.

Races *galeata* and *mitrata* sometimes considered separate species; also, though less frequently, *reichenowi*. Over 30 races described; traditional races *marchei*, *calleswaerti* and *blancum* now included in *galeata*; major, *metary*, *omochrysis*, *macrocristus*, *neumannii*, *torrensii*, *intermedia* and *uhenensis* included in *meleagris*; *ansorgei* included in *reichenowi*; *maxima*, *frommi*, *rikwae* and *bodalyae* included in *marungensis*; *papillata* included in *damarensis*; and *transvaalensis* and *limpopoensis* included in *cornuta*. Nine subspecies currently recognized.

Subspecies and Distribution.

N. m. subyi Hartert, 1919 - NW Morocco, between R Oum er Rhia and R Sebou.
N. m. galeata Pallas, 1767 - W Africa, E to S Chad and S to C Zaire and N Angola.
N. m. meleagris (Linnaeus, 1758) - E Chad E to Ethiopia, and S to N Zaire, Uganda and N Kenya.
N. m. somaliensis Neumann, 1899 - NE Ethiopia and Somalia.
N. m. reichenowi Ogilvie-Grant, 1894 - Kenya and C Tanzania.
N. m. mitrata Pallas, 1767 - W & E Tanzania S to E Mozambique, and W through Zambia and Zimbabwe to S Angola and N Botswana; Zanzibar and Tumbatu I.
N. m. marungensis Schadow, 1884 - S Congo Basin S to W Angola, and E in Zambezi Basin to Luangwa Valley, Zambia.
N. m. damarensis Roberts, 1917 - S Angola to Botswana and Namibia.
N. m. cornuta Gurney, 1868 - E South Africa.

Introduced to many parts of world, e.g. Cape Verde Is, SW Arabia, Madagascar and West Indies.

Descriptive notes. 53-63 cm; 1150-1600 g. Head and neck mostly featherless, with bare skin blue to bluish white; characteristic horn-coloured bony casque and variety of mainly red facial appendages, with black filoplumes on hindneck; plumage mainly blackish grey, with white spots and vermiculations. Female similar to male, but averages smaller. Juvenile plumage generally dull dark brown with feathers tipped reddish cream; casque, wattles etc. smaller; retains original down on head almost until adult plumage assumed. Races separated mainly on configuration of appendages on head and neck, including: density and

extent of filoplumes on hindneck; form and colour of cere; shape, size and colour of wattles; presence and form of cere bristles; size and shape of casque; and also breast colour.

Habitat. Wide variety of habitats mainly in open country, ranging from forest edge through savanna woodland to thorn-scrub, steppe and subdesert; particularly common in savanna with areas of cultivation interspersed. Local distribution limited by availability of drinking water, and suitable roosting sites, normally in trees or bushes. Occurs from sea-level up to above 3000 m. Often found in large numbers at water-holes.

Food and Feeding. Omnivorous. Plant food generally more important overall by volume, especially seeds, but also tubers, bulbs, roots, berries, flowers, leaves in cultivation, especially on fallen grain, causing some local conflict with farmers (see page 561). Invertebrates only consume average 12% of annual total by volume, but are preferred food when sufficiently abundant; mainly insects, particularly grasshoppers and termites, but wide variety recorded; also takes snails, ticks, worms, millipedes, etc. Forages on ground scratching with feet; also strips seeds from grass heads; ticks may be picked off backs of warthogs (*Phacochoerus africanus*).

Breeding. Season almost always in or just after rains, mainly Nov-Jan in S Africa, mostly May-Jul in W Africa, Mar-May in Morocco, Monogamous, but pair-bond not maintained during breeding season; in early part of season, male can attempt to mate with several different females. Nest is simple scrape in ground, lined with grass and feathers; usually situated in areas of long grass, and hidden under bush or tussock of grass, or in dense cover. Normally 8-12 eggs, incubated approx 20 laid on successive days; nests with large numbers of eggs (20-50) are probably always result of

laying by more than one female; replacement laying not recorded. Eggs usually yellowish to pale brown with darker speckling, but sometimes almost white; 44-58 x 36-42 mm. Incubation, starting when clutch complete, 24-28 days, by female only; hatching synchronous; chicks have down cinnamon-buff with dark streaks; can fly weakly at 14 days; fledging c. 4 weeks; chicks reach full adult weight by 30 weeks old; family groups join larger flocks when chicks 1-3 months old. Chick mortality generally rather high. Probably only one brood.

Movements. Sedentary. Home range of flock varies in size with habitat: averages smaller (0.8-1.8 km²) in primary woodland, larger (7.6-21.2 km²) in upland secondary woodland in Nigeria. Extent of local movements seems to be closely linked with proximity of roosting sites to sources of drinking water.

Status and Conservation. Not globally threatened. Mace-Lande: Safe; race *sabyi* possibly endangered. Total population probably numbers well over 1,000,000 birds; widespread and locally abundant; generally stable. Most races common to abundant, but some are severely affected locally by hunting and egg-collecting. However, because of wide habitat tolerance, species remains highly resilient; nevertheless, degradation of habitat, especially through use of pesticides, is major potential threat. Race *sabyi* may already be extinct; thought to number maximum 100 birds. Has undergone drastic decline for unknown causes; recently, only three records from 1970's, and no recent evidence of breeding. Formerly common in Forest of Mamou, whence no recent records; was also common on plateaux to S and SE, but now apparently confined to small area of Middle Atlas, if survives at all; thorough study needed, to establish current situation, and identify causes of decline, with a view to attempting to ensure survival of subspecies.

Bibliography. Angus & Wilson (1964), Ayeni (1979, 1980, 1981, 1983, 1984), Ayeni *et al.* (1983), Bannerman (1953), Benson (1960a), Berry & Crowe (1985), Brown & Britton (1980), Cramp & Simmons (1980), Crowe (1978c, 1979), Duffly (1992), Elbin *et al.* (1986), Farkas (1965), Ginn *et al.* (1989), Gratton (1971), Langrand (1990), Lever (1987), Mackworth-Praed & Grant (1957-1973), Maclean (1993), Maier (1982), Maier *et al.* (1983), Marx & Stoltz (1988), McGowan, Carroll & Ellis-Joseph (1994), Mentis *et al.* (1975), van Niekerk (1979, 1980, 1985), Penzhorn *et al.* (1991), Pinto (1983), Rutgers & Norris (1970), Siegfried (1965a, 1965b, 1966), Skeld (1962), Steyn & Tredgold (1967), Urban *et al.* (1986), Weise & Baxton (1967), Wolff (1976).

Genus *GUTTERA* Wagler, 1832

4. Plumed Guineafowl

Guttera plumifera

French: Pintade plumifère German: Schlichthauben-Perlhuhn Spanish: Pintada Plumifera

Taxonomy. *Numida plumifera* Cassin, 1857, Cape Lopez, Gabon.

Forms superspecies with *G. pucherani*. Races intergrade in NE Congo. Two subspecies recognized.

Subspecies and Distribution. *G. p. plumifera* (Cassin, 1857) - S Cameroon, N Congo and CN & S Central African Republic, S through N & W Gabon to N Angola (Cabinda).

G. p. schubotzi Reichenow, 1912 - N Zaïre E to W Rift Valley, S into forests W of L Tanganyika.

Descriptive notes. c. 45-51 cm. Bare skin of head and neck grey, including gape wattles and small occipital fold of skin; long black crest; plumage black spotted white, but lacking vermiculations; primaries chestnut, outer margin of outermost secondaries white. Female similar to male, but averages smaller. Juvenile has black down on head and neck; shorter crest; upperparts grey barred blackish; breast dusky with spotted and barred whitish. Race *schubotzi* has patches of orange skin in front of ear and on hindneck.

Habitat. Mainly restricted to primary forest; also occurs in very mature secondary growth.

Food and Feeding. Omnivorous: plant matter, such as seeds, roots, shoots, fruits and leaves; animals, especially invertebrates, including snails, slugs, millipedes, spiders and wide variety of insects, e.g. cockroaches, beetles, grasshoppers, crickets, Hemiptera, termites and ants. Forages on ground, scratching in soil and leaf litter with feet.

Breeding. Laying dates variable, and probably not seasonal, although drier months apparently avoided. Probably monogamous. Nest is small scrape on forest floor lined with dry leaves. Two clutches of 9 and 10 eggs. Eggs pale buff with many darkened pores; 47.5-53.3 x 37-39.9 mm. Incubation c. 23 days; chicks have down mainly buffy with dark longitudinal stripes.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Total population may number 10,000-100,000 birds. Generally appears to be rather uncommon, and probably unevenly distributed within its range. Apparently in decline as consequence of habitat loss and hunting pressure. Research needed on ecology of species, in order to establish requirements, and ultimately enable effective protection of sufficient area of prime habitat.

Bibliography. Bannerman (1953), Carroll (1988), Chapin (1932), Green, A.A. (1984), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1970), McGowan, Carroll & Ellis-Joseph (1994), Pinto (1983), Sargeant (1993), Thiollay (1985c), Urban *et al.* (1986).

5. Crested Guineafowl

Guttera pucherani

French: Pintade huppée German: Kriuselhauben-Perlhuhn Spanish: Pintada Montaña
(Other common names: Kenya Crested Guineafowl (*pucherani*); Crested Guineafowl (*edouardi*))

Taxonomy. *Numida pucherani* Hartlaub, 1860, Zanzibar.

Forms superspecies with *G. plumifera*. Formerly considered to constitute two separate species, with recognition of *G. edouardi* (Crested Guineafowl), which included all of present races, except nominate *pucherani* (Kenya Crested Guineafowl), but thorough analysis of morphological characters concluded that the two were conspecific. Several other races described: *sethsmithi*, *schoutedeni*, *pallasi*, *chapini* and *kathleenae* now included in *verreauxi*; *lividicollis* and *symensi* included in *edouardi*, and *graini* included in *pucherani*. Five subspecies normally recognized.

Subspecies and Distribution.

G. p. verreauxi (Elliot, 1870) - Guinea-Bissau E to NW Cameroon; E Congo E through Zaïre to W Kenya, and S to W & E Angola and W Zambia.

G. p. sclateri Reichenow, 1898 - NW Cameroon.

G. p. pucherani (Hartlaub, 1860) - SW Somalia W to EC Kenya, and S to C Tanzania, Zanzibar and Tumbatu I.

G. p. barbata Ghigi, 1905 - SE Tanzania S to E Mozambique and W to Malawi.

G. p. edouardi (Hartlaub, 1867) - E Zambia; Mozambique to NE South Africa (S to CE Natal).

Descriptive notes. 46-56 cm; male 721-1573 g. Bare skin of head and neck greyish blue, with patches of red or pale yellow on throat and around eye; iris red; well developed occipital skin fold; fairly long, bushy black crest; plumage black, spotted bluish white; primaries brown, outer margin of outermost secondaries white. Female similar to male, but averages smaller. Juvenile generally duller, finely barred black and white; bare skin much drabber. Races differ in colour of bare skin, especially in presence and extent of red on throat; also iris colour, brown in *verreauxi*; colour and form of occipital fold; shape and extent of crest; and presence and extent of black collar. Only nominate race has red skin round eye; *edouardi* lacks any red, and has whitish patch covering occipital fold; *sclateri* has crest short at front.

Habitat. Forest edge, secondary forest and gallery forest; also in forest-savanna mosaic. In NW Zambia, found in dense stands of pure *Cryptosepulum* woodland. Sometimes enters primary forest, where may coincide with *A. meleagrides*. Recorded up to 2200 m in Itombwe Mts, E Zaïre.

Food and Feeding. Omnivorous. Plant food includes seeds, fruits and berries of Rubiaceae, Amaranthaceae, Compositae, Malvaceae and Leguminosae; also shoots, stems, green leaves, bulbs and roots, e.g. of manioc. Animal food mainly invertebrates, including variety of insects (larval and adult beetles, grasshoppers, Hemiptera, flies, ants and termites), millepedes, spiders and small snails. Mainly forages on ground scratching in leaf litter and debris with feet, but has been seen eating fruit up trees; also follows troops of monkeys, feeding on fruit that they drop.

Breeding. Laying mainly during rains, but throughout year in equatorial zone; Nov-Feb in S Africa. Monogamous. Nest is scrape on ground with sparse lining, mainly of dead leaves and grass; usually well hidden, beside log or tree roots or under a bush. Normally 4-5 eggs, occasionally up to 7; clutches of 10-14 recorded in South Africa, but almost certainly with 2 females laying in same nest. Eggs deep buff to pinkish or white; 50-55 x 37.8-43.5 mm. Incubation c. 23 days, probably by female alone; chicks have down mainly buffy with dark longitudinal stripes; can fly at c. 12 days; fledging c. 30 days. Breeding success thought to be poor in general, as very few obviously immature birds seen in flocks during dry seasons.

Movements. Sedentary. Covers considerable distances during daily wanderings.

Status and Conservation. Not globally threatened. Mace-Lande: Safe. Total population may number over 100,000 birds. Shy habits and difficulty of observation may suggest species is less common and widespread than it really is; locally common in E South Africa. Population apparently stable overall, but may be affected locally by habitat loss and hunting. In Nigeria, increasing urbanization and also agricultural expansion, with planting of cocoa, oil palms, rubber, etc.; this, in conjunction with excessive and uncontrolled hunting, has led to certain reduction in range of species.

Bibliography. Ayeni (1979), Bannerman (1953), Berry (1972), Brooke (1984), Brown & Britton (1980), Crowe (1979), Ginn *et al.* (1989), Grimes (1987), Hill (1974), Lippens & Wille (1976), Louette (1981), Mackworth-Praed & Grant (1957-1973), Maclean (1993), McGowan, Carroll & Ellis-Joseph (1994), Pakenham (1979), Pinto (1983), Rutgers & Norris (1970), Thiollay (1985c), Urban *et al.* (1986), Wilson (1965).

Genus *ACRYLLIUM* G. R. Gray, 1840

6. Vulturine Guineafowl

Acryllium vulturinum

French: Pintade vulturine German: Geierperlhuhn Spanish: Pintada Vulturina

Taxonomy. *Numida vulturina* Hardwicke, 1834, West Africa; error = Tsavo, Kenya.

Monotypic.

Distribution. S Ethiopia, NW & SW Somalia and arid parts of N & E Kenya, S to R Pangani (NE Tanzania).

Descriptive notes. c. 60-72 cm; 1026-1645 g. Largest guinea-fowl. Noticeably long neck, legs and tail; bare skin of head and neck pale bluish grey, with patch of short, dense chestnut down on nape; well developed black and white hackles; plumage mainly dark grey, with white spots and vermiculations, and rich blue on underparts; commonly one or more spur-like bumps on each tarsus. Female similar to male, but averages smaller. Juvenile retains some of streaked natal down on head; hackles obvious; plumage generally greyish brown, with rufous-brown, buff and black barring and mottling; blue areas of plumage less

intensely coloured; lacks tarsal bumps.

Habitat. Generally found in drier and more open habitats than other guinea-fowl, especially semi-arid *Acacia/Commiphora* thorn-scrub and grassland with trees and bushes; arid and semi-arid plateau country. On Mt Marsabit, Kenya, found in montane forest; also in tall riverine *Acacia* woodland, when foraging; in areas of sympatry with *Guttera pucherani*, present species sometimes enters dense thickets. Exceptionally ranges as high as 1900 m.

Food and Feeding. Seeds and leaves of grasses and herbs; berries and fruit (*Commiphora*, *Ficus*), roots, bulbs, green buds and shoots. Also takes variety of insects, scorpions, spiders and small

molluscs. Mostly forages on ground, scratching with feet; occasionally climbs up into bushes and low trees (e.g. *Salvadora persica*, *Commiphora*) to feed on berries and fruits. Unlike other guineafowl does not appear to require drinking water, and even when water available in dry season, species does not drink.

Breeding. Probably breeds in or just after rainy season; laying peaks in Jun and Dec-Jan. Nest is simple scrape on ground, situated in cover of fairly dense grass, rock or bush. Up to 13-15 eggs, laid on successive days; eggs creamy white or pale brown, 49.5-55 x 37.3-41 mm. Incubation c. 23-25 days; chicks have yellowish buff down with dark brown mottling.

Movements. Sedentary.

Status and Conservation. Not globally threatened. Mace-Landé Safe. Total population may number over 1,000,000 birds. Generally common to abundant, and apparently stable; may suffer locally from overhunting. Seems to have disappeared from Uganda, where in past was recorded in N Karamoja.

Bibliography. Archer & Godman (1937), Ash & Miskell (1983), Britton (1980), Brewer & Britton (1980), Dekker (1971), Grahame (1969), Mackworth-Praed & Grant (1957), McGowan, Carroll & Ellis-Joseph (1994), Rogers & Norris (1970), Urban *et al.* (1986).

SUMMARY OF VOLUME 2

CATHARTIDAE (New World Vultures)
PANDIONIDAE (Osprey)
ACCIPITRIDAE (Hawks and Eagles)
SAGITTARIIDAE (Secretarybird)
FALCONIDAE (Caracaras and Falcons)
MEGAPODIIDAE (Megapodes)
CRACIDAE (Chachalacas, Guans and Curassows)
MELEAGRIDIDAE (Turkeys)
TETRAONIDAE (Grouse)
ODONTOPHORIDAE (New World Quails)
PHASIANIDAE (Partridges and Pheasants)
NUMIDIDAE (Guineafowl)

TECHNICAL DETAILS

- 310 x 240 mm
- 640 pages
- 60 colour plates
- 302 photographs
- 590 distribution maps
- more than 7000 bibliographical references
